

Alaskan Way Viaduct Replacement Project Discipline Report Instructions to Reviewers

Attached is the draft **Transportation Discipline Report** prepared for the Alaskan Way Viaduct Replacement Project Supplemental Draft Environmental Impact Statement (SDEIS). You have been asked to review this report because of your specialized knowledge of this subject. Please read and follow these instructions carefully.

Please note: Chapter 7 includes evaluation of the BAT lanes north of Roy Street as part of the 2030 Program. Text discussing this is **highlighted in yellow**. In the next version of this report, the 2030 Program results (highlighted sections) will be discussed qualitatively in less detail. This discussion should include some selected quantitative results, and to that end please use this review cycle to decide what those will be. Also, there are placeholders for some missing data to be provided later, including intersection LOS/delay for north portal area intersections affected by Option 2, and some travel times.

This discipline report will be the substantive foundation for the project's SDEIS and will be published as an appendix to the SDEIS. Following your review and subsequent revisions, these reports will be made available to cooperating and interested agencies. The final discipline report should:

- Describe studies, coordination, and methodology used to complete the study.
 - Include a complete, current description of the affected environment.
 - Evaluate impacts and mitigation (operation and construction) for these plans:
 - July 2009 plan set
 - AWV Bored Tunnel Construction Flowchart, October 1, 2009
1. Use the comment form provided. Draft materials are distributed as PDF files, or hard copy where requested. While this facilitates document distribution, it does not allow modification. Forms are provided for you to note your comments. All drafts are formatted with page and line numbers. Note these on the comment form in the columns provided to help us locate the subject of your comment. Your use of these forms will make it easier to compare and consolidate comments from multiple reviewers.

Assign a priority to each comment: Please assign each comment one of these priorities:

1. **Critical issue requiring inter-agency discussion**
 2. Factual or substantive error or issue that should be corrected prior to publication
 3. Editorial suggestion to improve readability or other idea
2. Make substantive, not editorial, comments. This is the first in our lead agency review cycles, so you have the opportunity to ensure that the analysis is complete and accurate. We are looking for comments on content and significant issues not yet identified in the report. Please do not spend time editing or proofreading; a technical editor will perform those tasks later. Feel free, however, to point out areas that need to be rewritten because the information needs clarification or is inaccurate. As a reviewer you should consider:
- Is the information factually correct?
 - Is the analysis complete and at the appropriate level of detail?
 - Is mitigation appropriate and sufficiently described?
 - Can it be clearly understood?

Your comments should have an explanation or accomplish a clear purpose. Comments without a good explanation may not be addressed.

3. Comments must be returned to **Angela Freudenstein** and **Mike Sallis** by **October 23, 2009**.

SR 99: ALASKAN WAY VIADUCT & SEAWALL REPLACEMENT PROGRAM

**Transportation Discipline Report
Alaskan Way Viaduct Replacement Project
Supplemental Draft EIS**

**Preliminary Draft
For Internal Review Only**

We respectfully request that the public not be given access to this document because FHWA has determined that this preliminary document is an intergovernmental exchange that may be withheld under the Freedom of Information Act. Premature release of this material to any segment of the public could give some sectors an unfair advantage and would have a chilling effect on intergovernmental coordination and the success of the cooperating agency concept.

Alaskan Way Viaduct & Seawall Replacement Program

Alaskan Way Viaduct Replacement Project

Supplemental Draft EIS

Transportation Discipline Report

Agreement No. Y-9715

Task CC.04

The Alaskan Way Viaduct Replacement Project is a joint effort between the Federal Highway Administration (FHWA), the Washington State Department of Transportation (WSDOT), and the City of Seattle. To conduct this project, WSDOT contracted with:

Parsons Brinckerhoff

999 Third Avenue, Suite 2200
Seattle, WA 98104

In association with:

16 A & G Consultants, Inc.	29 Mimi Sheridan, AICP
17 Berger/ABAM Engineers Inc.	30 Northwest Archaeological Associates, Inc.
18 Bolima Drafting & Design	31 Parametrix, Inc.

TABLE OF CONTENTS

1		
2	Chapter 1 Introduction and Summary	1
3	1.1 Introduction.....	1
4	1.2 Summary	3
5	1.2.1 Alternatives Studied	4
6	1.2.2 Alaskan Way Viaduct and Seawall Replacement Program	7
7	1.2.3 Summary of Findings	10
8	Chapter 2 Methodology	15
9	2.1 Study Area.....	15
10	2.2 Data Collection and Sources	15
11	2.2.1 Transportation Analyses	15
12	2.3 Travel Demand Estimates and Forecasts.....	17
13	2.3.1 Model Assumptions.....	17
14	2.3.2 Model Scenarios.....	18
15	2.4 Traffic Operations Analysis.....	20
16	2.4.1 Highway Simulation	20
17	2.4.2 Arterial Intersection Analysis	20
18	2.5 Transportation Data and Performance Measures.....	20
19	2.5.1 Sources of Existing Geometric Data and Traffic Control Information	20
20	2.5.2 Traffic Volume Information.....	23
21	2.5.3 Parking Inventory.....	24
22	2.5.4 Transit Service Routes and Frequencies.....	24
23	2.5.5 Ferry Service Characteristics at Colman Dock	24
24	2.5.6 Collision Data for SR 99	25
25	2.6 Analysis of Existing Conditions (Affected Environment)	25
26	2.6.1 Regional Context and Travel Patterns.....	25
27	2.6.2 Traffic Operations on SR 99.....	25
28	2.6.3 Traffic Operations at Key Arterial Intersections	26
29	2.6.4 Roadway Connectivity and Access	27
30	2.6.5 Transit Services.....	27
31	2.6.6 Truck Traffic and Freight.....	27
32	2.6.7 Parking	27
33	2.6.8 Pedestrians	27
34	2.6.9 Bicycles	27
35	2.6.10 Ferries	28
36	2.6.11 Collision History.....	28
37	2.7 Analysis of Future Conditions and Environmental Effects	28
38	2.7.1 Conditions in 2015 and 2030.....	28
39	2.7.2 Conditions in 2040	33
40	2.7.3 Construction Travel Conditions	33
41	2.8 Cumulative Effects.....	33

1	2.8.1 Program Elements	33
2	2.8.2 Other Projects	34
3	2.8.3 Changes in Travel Patterns and Systemwide Performance Measures.....	35
4	2.8.4 Traffic Operations on SR 99.....	35
5	2.8.5 Traffic Operations at Key Arterial Intersections	35
6	2.8.6 Travel Times	35
7	2.9 Determining Transportation Mitigation Measures	36
8	2.9.1 Operational Mitigation	36
9	2.9.2 Mitigation of Adverse Effects on Travel During Construction	36
10	Chapter 3 Studies and Coordination.....	39
11	3.1 Relevant Studies and Plans.....	39
12	3.1.1 City of Seattle Comprehensive Plan (2005)	39
13	3.1.2 City of Seattle Transportation Strategic Plan (2005)	39
14	3.1.3 City of Seattle Bicycle Master Plan (2007).....	39
15	3.1.4 City of Seattle Center City Circulation Report (2003)	39
16	3.1.5 City of Seattle Center City Access Strategy (2007).....	40
17	3.1.6 City of Seattle Freight Mobility Strategic Action Plan (2005 Plan Update)	40
18	3.1.7 Seattle Intermediate Capacity Transit Study (2001).....	40
19	3.1.8 City of Seattle Transit Plan (2005)	40
20	3.1.9 Seattle Streetcar Network Development Report (2008).....	41
21	3.1.10 Center City Parking Program Work Plan (2008)	41
22	3.1.11 Waterfront Parking Strategy Study (2002)	41
23	3.1.12 South Lake Union Transportation Study (Final Report, July 2004)	41
24	3.1.13 Destination 2030 Metropolitan Transportation Plan.....	41
25	3.1.14 Sound Transit 2 Plan (2008).....	42
26	3.1.15 King County Transit Now (2006).....	42
27	3.1.16 King County Metro 6-Year Transit Development Plan (2004).....	43
28	3.1.17 King County Ferry District – Technical Studies (2009)	43
29	3.1.18 Evaluation of Joint Operations in the Downtown Seattle Transit Tunnel (2001)	43
30	3.1.19 King County Metro Transit Tunnel Conversion Project Performance Reports (2005–2007).....	43
31	3.1.20 Alaskan Way Viaduct Project: Task 1 Report (December 1996).....	44
32	3.1.21 Washington State Transportation Plan 2007–2026 (November 2006).....	44
33	3.2 Coordination.....	44
34	Chapter 4 Affected Environment	45
35	4.1 Regional Context and Travel Patterns	45
36	4.1.1 SR 99	47
37	4.1.2 Other Freeways, Highways, and Expressways.....	47
38	4.1.3 Arterial and Local Streets.....	48
39	4.1.4 Travel Demand and Traffic Patterns	48
40	4.1.5 Roadway Connectivity and Access	54

1	4.2 Traffic Operations on SR 99	60
2	4.2.1 Alaskan Way Viaduct Mainline and Ramp Volumes.....	60
3	4.2.2 SR 99 Mainline Level of Service	64
4	4.2.3 SR 99 Mainline Speeds	67
5	4.3 Traffic Operations at Key Arterial Intersections	69
6	4.3.1 South.....	69
7	4.3.2 Central.....	70
8	4.3.3 North	71
9	4.4 Transit Services	72

Chapter 1 INTRODUCTION AND SUMMARY

1.1 Introduction

This discipline report evaluates the Bored Tunnel Alternative, the new alternative under consideration for replacing the Alaskan Way Viaduct. This report and the Alaskan Way Viaduct Replacement Project Supplemental Draft Environmental Impact Statement (EIS) that it supports are intended to provide new information and updated analyses to those presented in the March 2004 Alaskan Way Viaduct and Seawall Replacement Project Draft EIS and the July 2006 Alaskan Way Viaduct and Seawall Replacement Project Supplemental Draft EIS. The discipline reports present detailed technical analyses of existing conditions and predicted effects of the Bored Tunnel Alternative. The results of these analyses are presented in the main volume of the Supplemental Draft EIS.

The Federal Highway Administration (FHWA) is the lead federal agency for this project, primarily responsible for compliance with the National Environmental Policy Act (NEPA) and other federal regulations, as well as distributing federal funding. As part of the NEPA process, FHWA is also responsible for selecting the preferred alternative. FHWA will base their decision on the information evaluated during the environmental review process, including the Supplemental Draft EIS, to be followed by the Final EIS. FHWA can then issue their NEPA decision, called the Record of Decision (ROD), independent from the other agency recommendations.

The 2004 Draft EIS (WSDOT et al. 2004) evaluated five Build Alternatives and a No Build Alternative. In December 2004, the project proponents identified the cut-and-cover Tunnel Alternative as the preferred alternative and carried the Rebuild Alternative forward for analysis as well. The 2006 Supplemental Draft EIS (WSDOT et al. 2006) analyzed two alternatives—a refined cut-and-cover Tunnel Alternative and a modified rebuild alternative called the Elevated Structure Alternative. After continued public and agency debate, Governor Gregoire called for an advisory vote to be held in the City of Seattle. The March 2007 ballot included an elevated alternative and a surface-tunnel hybrid alternative. The citizens voted down both alternatives.

Following this election, the lead agencies committed to a collaborative process to find a solution to replace the viaduct along Seattle’s central waterfront. This Partnership Process is described in Appendix T, the Project History Report. In January 2009, Governor Gregoire, King County Executive Sims, and Seattle Mayor Nickels announced that the agencies had reached a consensus and recommended replacing the aging viaduct with a bored tunnel.

1 The environmental review process for the Alaskan Way Viaduct Replacement
2 Project (the project) builds on the five Build Alternatives evaluated in the 2004
3 Draft EIS and the two Build Alternatives evaluated in the 2006 Supplemental
4 Draft EIS. It also incorporates the work done during the Partnership Process. The
5 bored tunnel was not studied as part of the previous environmental review
6 process, and so it becomes the eighth alternative to be evaluated in detail.

7 The Bored Tunnel Alternative analyzed in this discipline report and in the
8 Supplemental Draft EIS has been evaluated both quantitatively and qualitatively.
9 The Bored Tunnel Alternative includes replacing State Route (SR) 99 with a bored
10 tunnel and associated improvements, such as relocating utilities located on or
11 under the viaduct, removing the viaduct, decommissioning the Battery Street
12 Tunnel, and making improvements to the surface streets in the tunnel's south and
13 north portal areas. For these project elements, the analyses of effects and benefits
14 have been quantified with supporting studies, and the resulting data are found in
15 the discipline reports (Appendices A through R). These analyses focus on
16 assessing the Bored Tunnel Alternative's potential effects for both construction
17 and operation, and considering appropriate mitigation measures that could be
18 employed. The Viaduct Closed (No Build Alternative) is also analyzed.

19 The Alaskan Way Viaduct Replacement Project is one of several independent
20 projects that improve safety and mobility along SR 99 and the Seattle waterfront
21 from the South of Downtown (SODO) area to Seattle Center. Collectively, these
22 individual projects are often referred to as the Alaskan Way Viaduct and Seawall
23 Replacement Program (the Program). This Supplemental Draft EIS evaluates the
24 cumulative effects of complementary projects referred to as the Program. Direct
25 and indirect environmental effects of these independent projects are considered
26 separately. This collection of projects is categorized into four groups: roadway
27 elements, non-roadway elements, projects under construction, and completed
28 projects.

29 Roadway Elements

- 30 • Alaskan Way Surface Street Improvements
- 31 • Elliott/Western Connector
- 32 • Mercer Street Improvements

33 Non-Roadway Elements

- 34 • First Avenue Streetcar
- 35 • Transit Enhancements
- 36 • Seawall Replacement
- 37 • Alaskan Way Promenade

1 **Projects Under Construction**

- 2 • S. Holgate Street to S. King Street Viaduct Replacement
- 3 • Transportation Improvements to Minimize Traffic Effects During
- 4 Construction
- 5 • Electrical Line Relocation along the Viaduct’s South End

6 **Completed Projects**

- 7 • Column Safety Repairs

8 **1.2 Summary**

9 This Transportation Discipline Report, Appendix C to the Alaskan Way Viaduct
10 Replacement Project Supplemental Draft EIS, describes transportation conditions
11 associated with the SR 99 corridor through the downtown Seattle area and predicts
12 transportation performance and impacts of the project and larger Alaskan Way
13 Viaduct and Seawall Replacement Program.

14 This Transportation Discipline Report comprises the following chapters:

15 Chapter 2, Methodology, describes the methods used to assess the alternatives in
16 this report.

17 Chapter 3, Studies and Coordination, provides information regarding agency
18 participation in the refinement of the project alternative.

19 Chapter 4, Affected Environment, includes discussion of current transportation
20 conditions.

21 Chapter 5, Operational Effects, Mitigation, and Benefits, describes changes in
22 travel patterns and traffic volumes for the following conditions:

- 23 1. 2015 Baseline (with the Alaskan Way Viaduct [AWV])
- 24 2. 2015 Viaduct Closed (No Build Alternative)
- 25 3. 2015 Project
- 26 4. 2030 Project

27 A brief discussion of 2040 conditions will provide a basis for describing further
28 changes in travel conditions beyond the horizon year.

29 Chapter 6, Construction Effects and Mitigation, reviews the construction plans for
30 the Bored Tunnel Alternative, traffic management approaches (detours), and
31 expected performance associated with major construction stages.

1 Chapter 7, Cumulative Effects, describes the secondary and cumulative effects of
2 the combined effect of the project (proposed action), other Program elements, and
3 other projects that are anticipated to affect transportation in the study area.

4 References consulted in the preparation of this report are provided in Chapter 8.

5 1.2.1 Alternatives Studied

6 The Bored Tunnel Alternative includes replacing SR 99 with the bored tunnel and
7 associated improvements, such as the relocation of those utilities located on or
8 under the viaduct; the removal of the viaduct, the decommissioning of the Battery
9 Street Tunnel, and improvements to the surface streets in the tunnel's south and
10 north portal areas. Also included are improvements to the Mercer Street corridor
11 from Dexter Avenue N. to Fifth Avenue N., and to Sixth Avenue N. from Denny
12 Way to Mercer Street. In addition, Broad Street would be closed from Taylor
13 Avenue N. to Ninth Avenue N. The Viaduct Closed (No Build Alternative) also is
14 analyzed.

15 Viaduct Closed (No Build Alternative)

16 Two scenarios are considered as part of the Viaduct Closed (No Build
17 Alternative), given the unpredictability associated with the long-term structural
18 viability of the viaduct:

- 19 • Scenario 1 – Sudden unplanned closure of the SR 99 viaduct due to
20 structural damage from a smaller earthquake or other reasons for partial
21 structural failures that render the viaduct unsafe or unusable.
- 22 • Scenario 2 – Catastrophic failure and collapse of the viaduct.

23 Scenario 1 is referred to as the Viaduct Closed (No Build Alternative) scenario in
24 this report. Scenario 2 is discussed qualitatively but is not quantitatively
25 analyzed in this report. The Transportation Discipline Report also analyzes traffic
26 and transportation conditions for continued operation of the current viaduct and
27 seawall. This scenario is referred to in this report as the Baseline. While this
28 scenario is useful for assessing the performance and effects of the Bored Tunnel
29 Alternative relative to the facility that is in place today, it should be recognized
30 that the current facility is reaching the end of its service life, is unlikely to remain
31 in satisfactory condition for long-term use, and is at risk of catastrophic failure in
32 an earthquake.

33 Bored Tunnel Alternative

34 The Bored Tunnel Alternative (the project) would be located generally under First
35 Avenue's current alignment, with access provided at a south portal near Qwest
36 and Safeco Fields between S. Royal Brougham Way and S. King Street. Ramps
37 providing northbound on, northbound off, southbound on, and southbound off

1 movements to and from SR 99 would also be constructed in this area. New
2 surface streets would be constructed between S. Royal Brougham Way and
3 S. King Street. Three new streets, S. Plummer, S. Charles, and S. Dearborn Streets,
4 would connect First Avenue S. and Alaskan Way.

5 There are three primary components of the Bored Tunnel Alternative: the south
6 portal area, the bored tunnel, and the north portal area. Each of these areas is
7 discussed in more detail below.

8 South Portal Area

9 Full northbound and southbound access to/from SR 99 would be provided in the
10 south portal area near S. Royal Brougham Way. The northbound off-ramp from
11 SR 99 connecting to Alaskan Way would have a general purpose lane and a peak
12 hour transit-only lane to accommodate transit coming from south or West Seattle.

13 Surface streets would be reconfigured and improved in the south portal area. The
14 southbound on-ramp and northbound off-ramp to SR 99 would feed directly into
15 a reconfigured Alaskan Way surface street. Along this section, Alaskan Way
16 would have three lanes in each direction. A left-hand turn pocket for southbound
17 traffic would be provided at most intersections. The newly configured Alaskan
18 Way would have three new intersections and cross-streets. The new cross-streets
19 would be built west of Qwest Field and would be named S. Plummer, S. Charles,
20 and S. Dearborn Streets. The cross-streets would have sidewalks on both sides.
21 The reconfigured Alaskan Way would have a sidewalk on the west side and a
22 minimum 25-foot-wide multi-use path, called the City Side Trail, on the east side.
23 The City Side Trail would travel from S. Atlantic Street up to S. King Street.

24 The new East Frontage Road east of SR 99 would be widened slightly at
25 S. Atlantic Street to accommodate truck turning movements, and a new right-turn
26 pocket would be added between S. Atlantic Street and S. Royal Brougham Way.

27 Central: Bored Tunnel Alignment – S. King Street to Denny Way

28 The bored tunnel would begin at approximately Railroad Way S. and would
29 continue to John Street. The tunnel would generally travel under First Avenue up
30 to Pine Street, where it would curve slightly to the northeast to approximately
31 John Street.

32 The tunnel would have two lanes in each direction. Southbound lanes would be
33 located on the top portion of the tunnel, and the northbound lanes would be
34 located on the bottom. Travel lanes would be approximately 12 feet wide, with a
35 2-foot-wide shoulder on one side and an 8-foot-wide shoulder on the other side.
36 The wider shoulder would provide emergency vehicle access and space for
37 disabled vehicles to safely stop.

1 The wider shoulder would also provide access to emergency tunnel exits, which
2 would be provided at least every 650 feet. In an emergency, travelers would walk
3 along the shoulders to reach a doorway into a secure waiting area, called a refuge
4 area, located between the tunnel's levels. Staircases inside the refuge area would
5 provide access between the roadway levels. Signs would point travelers to the
6 nearest exit where they would wait for assistance or walk out of the tunnel.
7 Refuge areas would contain emergency telephones.

8 The tunnel would be equipped with ventilation, a fire detection and suppression
9 system, and drainage. Video cameras would provide real-time information to
10 operators at the Washington State Department of Transportation (WSDOT)
11 24-hour tunnel control center and allow them to respond quickly to changing
12 conditions and emergencies. The tunnel control center would be incorporated
13 into the tunnel ventilation building at either the south or north tunnel portal.

14 North Portal Area – Options 1 and 2

15 Full northbound and southbound access to/from SR 99 would be provided near
16 Harrison and Republican Streets. The existing on- and off-ramps provided at
17 Denny Way would be closed and replaced with downtown access ramps to/from
18 SR 99 that drivers would access via a new surface connection between Denny
19 Way and Harrison Street.

20 Northbound access from SR 99 and southbound access to SR 99 would be
21 provided via new ramps at Republican Street. The northbound off-ramp to
22 Republican Street would be provided on the east side of SR 99 and a southbound
23 on-ramp would be provided on the west side of SR 99. The northbound off-ramp
24 would be routed to an intersection at Dexter Avenue N. Drivers would access the
25 southbound on-ramp via a new connection at Sixth Avenue N.

26 Surface streets would be reconfigured and improved in the north portal area. The
27 street grid between Denny Way and Harrison Street would be reconnected by
28 building a new north-south street over the top of SR 99 (referred to as surface
29 Aurora Avenue) and connecting John, Thomas, and Harrison Streets as cross-
30 streets. The new north-south roadway would have two general purpose lanes in
31 each direction, a transit only lane, and turn pockets between Denny Way and
32 Harrison Street. Signalized intersections would be located at Denny Way and
33 John, Thomas, and Harrison Streets.

34 John Street would be built with one lane in each direction, a center turn lane, and
35 bike lanes and sidewalks on each side of the roadway. Thomas Street would be
36 built with one lane in each direction, a center turn lane, and sidewalks. Harrison
37 Street would be built with two lanes in each direction and sidewalks.

1 Mercer Street would become a two-way street and would be widened from
 2 Dexter Avenue N. to Sixth Avenue N. The rebuilt Mercer Street would have three
 3 lanes in each direction with left-hand turn pockets. Broad Street would be filled
 4 and closed between Ninth Avenue N. and Taylor Avenue N.

5 Two configurations for Sixth Avenue N. and the southbound on-ramp are being
 6 considered:

- 7 • Option 1 proposes to build a new roadway that would extend Sixth
 8 Avenue N. from Harrison Street to Mercer Street in a typical grid
 9 formation. The new roadway would have two lanes in each direction with
 10 signalized intersections at Republican and Mercer Streets.
- 11 • Option 2 proposes to build a new roadway that would extend Sixth
 12 Avenue N. in a curved formation between Harrison and Mercer Streets.
 13 The new roadway would have two lanes in each direction and a
 14 signalized intersection at Republican Street.

15 Viaduct Removal and Battery Street Tunnel Decommissioning

16 Following completion of the new SR 99 bored tunnel, the existing viaduct would
 17 be removed. Utilities located on the viaduct and, where necessary, those under
 18 the viaduct would be relocated and the Battery Street Tunnel would be
 19 decommissioned. The demolition of the existing Alaskan Way Viaduct from
 20 S. King Street to Battery Street would take approximately 9 months.

21 **1.2.2 Alaskan Way Viaduct and Seawall Replacement Program**

22 This Supplemental Draft EIS evaluates the short and long-term environmental
 23 effects of the project and the cumulative effects of complementary projects
 24 referred to as the Program. Exhibit 1-1 lists the project and Program elements.

25 **Exhibit 1-1. Project and Program Elements**

Bored Tunnel Alternative	Cumulative Effects (Program)	
	Other Roadway Elements	Non-Roadway Elements
- Remove viaduct - Replace SR 99 with tunnel or other limited-access facility - Relocate utilities located on viaduct - Surface streets at south portal - Surface streets at north portal (Mercer Street from Dexter Avenue to Fifth Avenue, Sixth Avenue reconnection, remove Broad Street) - Decommission Battery Street Tunnel	- Alaskan Way surface street (on location of former viaduct) from S. King Street to Pike Street - Elliott/Mercer Connector from Pike Street to Battery Street - Mercer Street west corridor improvements (Fifth Avenue to Elliott Avenue)	- Replace seawall - Develop Alaskan Way promenade - First Avenue Streetcar - Enhanced transit service

1 **Roadway Elements**

2 Alaskan Way Surface Street Improvements

3 The Alaskan Way surface street would be rebuilt and improved between S. King
4 Street and Pine Street. The new surface street would be six lanes wide between
5 S. King and Columbia Streets (not including turn lanes), transitioning to four
6 lanes between Marion and Pike Streets. Generally, the new street would be
7 located east of the existing street where the viaduct is located today. The new
8 street would include sidewalks, bike lanes, parking/loading zones, and signalized
9 pedestrian crossings at cross streets. The existing waterfront streetcar would be
10 replaced by a new streetcar line running on First Avenue. The new surface street
11 would provide a regional truck route for freight traveling to/from the Duwamish/
12 Harbor Island/SR 519 area and the Ballard Interbay Northend Manufacturing and
13 Industrial Center (BINMIC).

14 Elliott/Western Connector

15 The Elliott/Western Connector would provide a connection from the Alaskan
16 Way surface street to the Elliott/Western corridor that provides access to/from
17 BINMIC and neighborhoods north of Seattle (including Ballard and Magnolia).
18 The connector would be four lanes wide and would provide a grade-separated
19 crossing of the BNSF mainline railroad tracks. Additionally, it would provide
20 local street access to Pike Street and Lenora Street and integrate back into the
21 street grid at Bell Street, which would improve local street connections in
22 Belltown. The new roadway would include bicycle and pedestrian facilities.

23 Mercer Street West Corridor Improvements

24 The Mercer Street west corridor improvements include reconfiguring Mercer
25 Street between Fifth Avenue N. and Elliott Avenue to accommodate two-way
26 traffic. The route would be redesignated by the City as a regional truck route to
27 provide vital freight connections to Ballard/Interbay. These improvements would
28 provide access to Ballard/Interbay freight and drivers coming from Ballard and
29 Magnolia. Additionally, Roy Street from Aurora Avenue to Queen Anne Avenue
30 would be reconfigured to accommodate two-way traffic.

31 **Non-Roadway Elements**

32 First Avenue Streetcar

33 Functioning as a local connector, the First Avenue Streetcar would circulate
34 between S. Jackson Street and Republican Street. This alignment would travel
35 within several of Seattle's densest neighborhoods, including Pioneer Square, the
36 Commercial Core and Central Business District (CBD), Belltown, and Uptown
37 (Lower Queen Anne). Additionally, it would serve many tourist and regional

1 attractions, such as Pike Place Market, the Seattle waterfront piers, Seattle Art
2 Museum, Seattle Aquarium, and the Olympic Sculpture Park.

3 Transit Enhancements

4 A variety of transit enhancements would be provided to support planned
5 transportation improvements associated with the Program. This includes (1) the
6 Delridge RapidRide line, (2) additional service hours on the West Seattle and
7 Ballard RapidRide lines, (3) peak-hour express routes added to South Lake Union
8 and Uptown, and (4) local bus changes (such as realignments and a few
9 additions) to several West Seattle and northwest Seattle routes. Additionally,
10 northbound and southbound right-side transit lanes on SR 99 are assumed from
11 just south of the Aurora Bridge to north of Aloha Street.

12 Seawall Replacement

13 The Alaskan Way Seawall Replacement Project is a rehabilitation effort to protect
14 the shoreline along Elliott Bay, including Alaskan Way, from seawall failure due
15 to seismic and storm events. The project limits extend from S. Washington Street
16 in the south to Broad Street in the north.

17 Alaskan Way Promenade

18 A new expanded promenade and public space would be provided to the west of
19 the new Alaskan Way surface street between S. King Street and Pike Street. The
20 promenade would vary in width and would serve Piers 48 through 59, which
21 have varying uses, including cruise ship and ferry terminals, restaurants, retail
22 shops, hotels, and regional entertainment such as the Seattle Aquarium. Access to
23 the piers would be provided by service driveways.

24 Between Marion and Pike Streets, the promenade would be approximately 70 to
25 80 feet wide. This public space will be designed at a later date. Other potential
26 open space sites include a triangular space north of Pike Street and east of
27 Alaskan Way, and parcels created by the removal of the viaduct between Lenora
28 and Battery Streets.

29 **Projects Under Construction**

30 S. Holgate Street to S. King Street Viaduct Replacement Project

31 The S. Holgate Street to S. King Street Viaduct Replacement Project will replace
32 this seismically vulnerable portion of SR 99 with a seismically sound structure
33 that is designed to current roadway and safety standards. An Environmental
34 Assessment for this project was completed in June 2008, and the Finding of No
35 Significant Impact was published in February 2009. Construction and early utility

1 relocations began in mid-2009 and is the project expected to be completed at the
2 end of 2014.

3 Transportation Improvements to Minimize Traffic Effects During Construction

4 Several transportation improvements are underway to help offset traffic effects
5 during construction of projects included in the Program. Construction or
6 implementation of the following improvements is underway:

- 7 • Adding variable speed signs and travel time signs on Interstate 5 (I-5) to
8 help maximize safety and traffic flow.
- 9 • Providing funding for the Spokane Street Viaduct Widening Project,
10 which includes a new Fourth Avenue S. off-ramp for West Seattle
11 commuters.
- 12 • Adding buses and bus service in the West Seattle, Ballard/Uptown, and
13 Aurora Avenue corridors during construction, as well as a bus travel time
14 monitoring system.
- 15 • Upgrading traffic signals and driver information signs for the Denny Way,
16 Elliott Avenue W./15th Avenue W., SODO, and West Seattle corridors to
17 support transit and traffic flow.
- 18 • Providing information about travel alternatives and incentives to
19 encourage use of transit, carpool, and vanpool programs.

20 **Completed Projects**

21 Column Safety Repairs

22 Construction to strengthen four column footings between Columbia Street and
23 Yesler Way was completed in April 2008. To prevent the columns from sinking
24 further, crews drilled a series of steel rods surrounded by concrete into stable soil,
25 and then added a layer of reinforced concrete to tie the new supports to the
26 existing column footings.

27 Electrical Line Relocation Along the Viaduct's South End

28 Construction to relocate electrical lines began in September 2008 and was
29 completed in fall 2009. WSDOT and Seattle City Light are relocating electrical
30 lines from the viaduct to underground locations east of the viaduct between
31 S. Massachusetts Street and Railroad Way S.

32 **1.2.3 Summary of Findings**

33 Operational benefits of the Bored Tunnel Alternative can be seen both in
34 comparison to the Baseline scenario as well as the Viaduct Closed (No Build
35 Alternative). The Baseline itself would have improved access in the south end

1 area in comparison to existing conditions with the addition of the stadium area
2 ramps to/from the south. The Viaduct Closed (No Build Alternative), however,
3 would substantially reduce mobility throughout the corridor and result in highly
4 congested conditions along Alaskan Way surface street as well as downtown
5 arterials. Travel times between Woodland Park and Spokane Street for the PM
6 peak hour would be expected to triple compared to the Baseline. I-5 also would
7 be expected to have increased congestion with the Viaduct Closed (No Build
8 Alternative).

9 The Bored Tunnel Alternative is projected to experience some decrease in
10 performance in overall conditions compared to the Baseline, but conditions
11 would be substantially better than the Viaduct Closed (No Build Alternative).
12 SR 99 through traffic is expected to operate better than Baseline due to the
13 removal of the merging and weaving conflicts associated with the Elliott/Western
14 ramps and the midtown ramps.

15 Peak hour travel times for SR 99 through trips are projected to be 9 to 25 percent
16 faster than under Baseline depending on the peak hour and direction, and three
17 times as fast as for the Viaduct Closed (No Build Alternative). Regarding other
18 key peak hour travel time routes analyzed, the Bored Tunnel Alternative is
19 projected to be about 1 minute slower than the Baseline between West Seattle and
20 downtown Seattle due to the removal of the midtown ramps. Between Ballard
21 and Spokane Street, the Bored Tunnel Alternative using the Alaskan Way surface
22 street route is expected to be 2 to 8 minutes slower than Baseline, which includes
23 the existing Elliott/Western ramps. The Bored Tunnel Alternative's travel times
24 along this route would be compromised due to the lack of a connection from
25 Elliott/Western Avenues to the waterfront, causing traffic to use Broad Street,
26 which includes an at-grade rail crossing. However, using Mercer Street and the
27 bored tunnel, the Bored Tunnel Alternative is expected to be only 1 to 2 minutes
28 slower in the AM peak hour, and in the PM peak hour less than a minute slower
29 southbound, and a minute faster northbound.

30 The main points expected for each scenario are summarized below.

31 2015 Baseline

- 32 • Access would be improved in the south end due to the S. Holgate Street
33 to S. King Street Viaduct Replacement Project interchange, compared to
34 existing conditions.
- 35 • There would be heavy traffic on Alaskan Way surface street between
36 S. King Street and Marion Street.
- 37 • First Avenue S. and S. Atlantic Street would operate at level of service
38 (LOS) E/F (AM/PM).

- 1 • Travel times would likely be a little higher than existing conditions.
- 2 • Mercer Street/Fairview Avenue N. would be problematic in the PM peak
- 3 period for all scenarios.

4 **2015 Viaduct Closed (No Build Alternative)**

- 5 • There would be a high level of congestion throughout the corridor.
- 6 • Alaskan Way surface street would be severely congested.
- 7 • North/south CBD arterials would be substantially affected.
- 8 • I-5 is likely to experience the greatest increase in traffic of all alternative
- 9 scenarios.
- 10 • Travel times in general are likely to be much higher than in 2015
- 11 Baseline.
- 12 • The interface of Alaskan Way traffic with Seattle Ferry Terminal traffic at
- 13 Colman Dock would be problematic.

14 **2015 Bored Tunnel Alternative**

- 15 • There would be some decreased performance in overall conditions
- 16 compared to Baseline, but conditions would be substantially better than
- 17 under the Viaduct Closed (No Build Alternative).
- 18 • SR 99 through traffic is expected to operate better than Baseline and
- 19 would be greatly improved over Viaduct Closed (No Build Alternative).
- 20 • LOS at First Avenue S./S. Atlantic Street would be expected to improve
- 21 in the AM peak period as compared to the Baseline.
- 22 • Connection of east/west streets across Aurora Avenue in the South Lake
- 23 Union area would improve local circulation and mobility for motorized
- 24 vehicles and nonmotorized modes.
- 25 • Extension of Sixth Avenue N. to Mercer Street would improve access to
- 26 southbound SR 99 from Mercer Street. This improvement is increased
- 27 with Option 1 as compared to Option 2.
- 28 • I-5 traffic would be similar to Baseline.
- 29 • Outside of the SR 99 through traffic, where travel times are faster than
- 30 Baseline, travel times would be similar or somewhat slower than
- 31 Baseline, but substantially improved over Viaduct Closed (No Build
- 32 Alternative).
- 33 • Alaskan Way surface street would likely experience heavier traffic than
- 34 Baseline but still would be improved over Viaduct Closed (No Build
- 35 Alternative).

- 1 • Travel along Alaskan Way at the Seattle Ferry Terminal at Colman Dock
2 could be problematic during peak ferry loading.
- 3 • The waterfront route would be compromised due to lack of an
4 Elliott/Western Connector and the rail crossing at Broad Street.
- 5 • Heavier volumes would be seen on First Avenue through Pioneer Square
6 in comparison to Baseline.

7 North Portal Area: Option 1

- 8 • Option 1 would provide all movements at Sixth Avenue N./Mercer
9 Street.
- 10 • Option 1 would provide an additional route from downtown to Uptown,
11 and a more direct route than Option 2 from I-5 to southbound SR 99.
- 12 • Option 1 would provide a pedestrian and bike crossing at Sixth
13 Avenue N., connecting to the proposed trail along the north side of
14 Mercer Street.

15 North Portal Area: Option 2

- 16 • Option 2 would move the intersection closer to Dexter Avenue N. and
17 immediately adjacent to the Aurora Avenue overcrossing.
- 18 • The signal would be problematic due to proximity to Dexter Avenue N.
19 and sight distance issues westbound due to the Aurora Avenue
20 overcrossing. Hence, Option 2 would likely allow right turns only in and
21 out of Sixth Avenue N and would not be signalized.
- 22 • Option 2 would not provide an additional downtown-to-Uptown route.
- 23 • To travel from I-5 to SR 99 southbound, drivers would need to take either
24 Dexter Avenue N. to Harrison Street to the Republican Street on-ramp or
25 Taylor Avenue N. to Roy Street to SR 99.
- 26 • This option would not provide a pedestrian and bike crossing at Sixth
27 Avenue N.

28 **2015 Partial Program**

- 29 • The Partial Program is projected to experience similar or better overall
30 performance as compared to the project.
- 31 • The waterfront route would be improved due to the Elliott/Western
32 Connector and widened Alaskan Way surface street.
- 33 • The westbound Mercer Street route would be improved with two-way
34 Mercer Street west of Fifth Avenue N.

1 **2015 Program**

- 2 • Increased RapidRide service from West Seattle and Ballard would
3 increase ridership along those routes.
- 4 • The transit lane on SR 99 between Aurora Bridge and Aloha Street may
5 attract additional ridership, but is likely to substantially impair overall
6 traffic operations, including creating backups into the northbound tunnel
7 as well as southbound across the Aurora Bridge, and affecting the ability
8 of transit to access the left side off-ramp to Denny Way.

9 **Construction**

- 10 • Two lanes in each direction would be maintained on SR 99.
- 11 • Access to/from SR 99 would be maintained in all areas where current
12 access exists.
- 13 • Traffic levels are projected to be reduced between 20 and 30 percent on
14 SR 99 (Spokane Street to Mercer Street) in comparison to the 2015
15 Baseline Alternative.
- 16 • Peak period traffic speeds and travel times on SR 99 are expected to be
17 only slightly slower than Baseline.
- 18 • Some peak period traffic is expected to divert to north/south arterials and
19 I-5 and/or other time periods.
- 20 • Heavier volumes would use First Avenue through Pioneer Square.

21 **2030 Project and Program**

22 By 2030, there would be similar patterns as in the 2015 Project and Program,
23 except with slightly lower performance due to overall traffic growth.

Chapter 2 METHODOLOGY

This chapter details the transportation data collection process, specifies the methods for performing travel forecasting and traffic analysis, and describes the types of transportation effects investigated and how those effects were evaluated.

2.1 Study Area

The study area for transportation encompasses the project area and nearby transportation facilities that are related to or affected by the SR 99 corridor. The study area is very similar to that used in previous EIS studies, such as the 2006 Supplemental Draft EIS (see Exhibit 2-1). It is generally bounded by S. Spokane Street to the south, Elliott Bay to the west, Aloha Street (three blocks north of Mercer Street) to the north, and I-5 to the east.

The potential for cumulative effects is considered for the broader region.

2.2 Data Collection and Sources

2.2.1 Transportation Analyses

The Transportation Research Board's 2000 *Highway Capacity Manual* (HCM) provides guidance for assessing traffic operating conditions for the range of roadway types found within the study area, including limited-access segments and ramps on SR 99, as well as signalized and unsignalized intersections on study area arterials.

The *National Cooperative Highway Research Report #255, Highway Traffic Data for Urbanized Area Project Planning and Design* (Transportation Research Board 1982) outlines recommended practices for preparation of transportation data, including travel forecasts.

In addition, design guidelines that are relevant to the study of transportation conditions include the following:

- *A Policy on Geometric Design of Highways and Streets, 5th Edition* (AASHTO 2004a).
- *A Guide for Achieving Flexibility in Highway Design, 1st Edition* (AASHTO 2004b).
- *Guide for the Development of Bicycle Facilities, 3rd Edition* (AASHTO 1999).
- *Manual on Uniform Traffic Control Devices, 3rd Edition* (FHWA 2003).
- *Design Manual* (WSDOT 2009).
- Any relevant City of Seattle design guidelines/standards.

Exhibit 2-1 Study Area

1 2.3 Travel Demand Estimates and Forecasts

2 A regional travel demand model was used for this study to support assessment of
3 future conditions. The project model is based on the current (2008) Seattle
4 Department of Transportation (SDOT) enhanced version of the Puget Sound
5 Regional Council (PSRC) regional planning model, which operates in the EMME
6 software environment. The model reflects assumptions for regional population
7 and employment growth as defined in PSRC's adopted regional plan, *Destination*
8 *2030, the Metropolitan Transportation Plan for the Central Puget Sound Region* (PSRC
9 2001). These data were most recently updated in 2006.

10 Documentation of model development and validation is detailed in three
11 documents:

- 12 • *PSRC Travel Model Documentation (for Version 1.0), Updated for Congestion*
13 *Relief Analysis, Final Report* (PSRC 2007a).
- 14 • *Alaskan Way Viaduct (AWV) Central Waterfront Travel Demand Model*
15 *Documentation* (Fehr and Peers 2008).
- 16 • *Alaskan Way Viaduct & Seawall Replacement Program Travel Demand Model*
17 *Refinement and Validation Report* (Parsons Brinckerhoff 2009).

18 The travel demand model was used to establish baseline traffic estimates for
19 future years that reflect forecast population and employment changes, as well as
20 planned transportation system improvements. Horizon year forecasts were
21 developed for 2030 conditions, while forecasts for the year of opening and the
22 construction period were derived from model runs for 2015.

23 2.3.1 Model Assumptions

24 The future year model scenarios include a unique set of baseline assumptions for
25 each horizon year (e.g., 2015, 2030). These assumptions include population and
26 employment forecasts for the specific horizon year and transportation network
27 elements, including today's highway, street, and transit system components as
28 well as other transportation improvements that are currently identified in
29 adopted regional plans and have a funding commitment toward implementation
30 in place.

31 In addition to using the PSRC four-county EMME travel demand forecasting
32 model assumptions for population and employment to develop future year
33 forecasts, the project team compiled a list of transportation projects that are
34 included in the baseline and build networks and have worked with the lead
35 agencies to finalize and reach consensus on these assumptions. The current list of
36 major new transportation system components for 2030 is as follows:

- 1 • New ramps to/from Alaskan Way south of S. King Street and
2 reconfiguration of Alaskan Way S. and S. Atlantic Street as proposed in
3 the SR 99 S. Holgate Street to S. King Street Viaduct Replacement Project.
- 4 • Sound Transit Phase 1 and 2: Sounder Commuter Rail; ST Express Bus;
5 First Hill Streetcar; and South Link, University Link, North Link, and East
6 Link light rail.
- 7 • Existing transit services and new services proposed in agencies' 6-year
8 plans.
- 9 • Third Avenue transit exclusivity (Stewart Street to Yesler Way) and the
10 Fourth Avenue S. bus island north of S. Jackson Street (continuation of
11 improvements put in place for Sound Transit Tunnel Conversion).
- 12 • King County Transit Now service changes and bus rapid transit (BRT)
13 corridors (called RapidRide) approved through Transit Now (2006).
- 14 • SR 519 Intermodal Access Project, Phase 2.
- 15 • The Two-way Mercer Corridor Project, which would widen Mercer Street
16 between I-5 and Dexter Avenue N. to accommodate three lanes of travel in
17 each direction, parking, sidewalks, and a median with left-turn lanes.
- 18 • Spokane Street Viaduct Project, including widening between Sixth
19 Avenue S. and SR 99, relocation of westbound off-ramp from Fourth
20 Avenue S. to First Avenue S., and new eastbound off-ramp at Fourth
21 Avenue S.

22 The 2015 model has similar components as the 2030 model, but does not include
23 Sound Transit Phase 2 (ST2) elements (North Link or East Link).

24 Based on input from King County Metro, the model assumes fall 2009 service
25 levels as a year 2015 baseline for transit due to the national recession and sales tax
26 revenues being substantially less than predicted in the 2009 budget.

27 The assumptions for Port of Seattle container terminal/rail terminal trips
28 (Terminal 46, Terminal 30, and the North Seattle International Gateway [SIG], in
29 particular) in the SR 99: S. Holgate Street to S. King Street Viaduct Replacement
30 Project are included in the analysis in the post-processing portion of volume
31 development (i.e., they were incorporated into the volumes after the travel
32 demand model runs, but prior to any operational analyses). The PSRC 2040
33 freight element is not incorporated into the travel demand model at this point.

34 **2.3.2 Model Scenarios**

35 A baseline model for 2015 was prepared that included the baseline elements
36 described previously. The Baseline scenario assumes that the existing viaduct
37 would remain in place in its current configuration except for new ramps to/from

1 Alaskan Way south of S. King Street and reconfiguration of Alaskan Way S. and
2 S. Atlantic Street as proposed in the SR 99 S. Holgate Street to S. King Street
3 Viaduct Replacement Project. The 2015 Baseline scenario serves as a reference
4 point to compare both the Viaduct Closed (No Build Alternative) and the Bored
5 Tunnel Alternative. The Viaduct Closed (No Build Alternative) assumes that the
6 existing viaduct would not be in service from S. Royal Brougham Way to the
7 south portal of the Battery Street Tunnel, with SR 99 instead connecting to the
8 existing street grid at these locations. The existing linkage from the central
9 waterfront to Battery Street Tunnel provided by the Alaskan Way Viaduct would
10 not be replicated. The Alaskan Way surface street would be maintained in its
11 current alignment, but restriped to provide four travel lanes.

12 A 2015 build scenario was developed to gauge year-of-opening conditions that
13 include network changes associated with the Bored Tunnel Alternative.
14 Additionally, one 2015 construction scenario was developed to reflect conditions
15 during the most disruptive construction phase. The Bored Tunnel Alternative
16 was also modeled for design year (2030) conditions. A “high-level” year 2040
17 assessment was conducted by analyzing projected population and employment
18 growth in the region and in the Center City area. This assessment did not require
19 travel demand model runs. Two 2015 networks and one 2030 network were
20 modeled to analyze cumulative effects as well. In total, nine model runs were
21 conducted reflecting the following conditions:

- 22 1. Existing Conditions (used for model calibration)
- 23 2. 2015 Baseline (with AWV)
- 24 3. 2015 Viaduct Closed (No Build Alternative)
- 25 4. 2015 Bored Tunnel Alternative
- 26 5. 2015 Partial Program (Bored Tunnel Alternative plus all Program elements
27 except the First Avenue Streetcar and King County Metro transit
28 improvements – Cumulative Effects)
- 29 6. 2015 Program (Bored Tunnel Alternative plus all Program elements –
30 Cumulative Effects)
- 31 7. 2030 Bored Tunnel Alternative
- 32 8. 2030 Program (Cumulative Effects)
- 33 9. 2015 Construction

1 **2.4 Traffic Operations Analysis**

2 **2.4.1 Highway Simulation**

3 SR 99 traffic operations were assessed for the AM and PM peak hours using a
4 traffic simulation model developed in the VISSIM modeling environment
5 (version 5.1). The VISSIM model includes mainline SR 99 segments, ramps, and
6 ramp terminal intersections. The model replicates traffic flow by simulating
7 discrete vehicle movements to produce estimates of travel speeds and traffic
8 density, which can be used to assess highway LOS consistent with HCM
9 definitions.

10 **2.4.2 Arterial Intersection Analysis**

11 Intersection traffic operations were evaluated for key locations on the arterial
12 network using models developed in Trafficware Corporation’s Synchro software
13 (version 7.0 or later). Synchro is a traffic modeling program designed for analysis
14 of intersection traffic operations and the optimization of traffic signal timings.
15 Synchro reports average vehicle delay, allowing calculation of LOS consistent
16 with HCM definitions. Synchro also estimates average and maximum queue
17 lengths. In addition, many intersections were also analyzed using the VISSIM
18 model (as described previously).

19 Intersections were selected for analysis based primarily on relation to the AWW
20 corridor and changes in traffic patterns predicted by the travel forecasting model.
21 These included ramp termini, new or revised intersections (including those along
22 Alaskan Way), and other intersections in the study area that would experience
23 substantial increases in traffic (approximately 100 vehicles per hour per lane or
24 more and an increase of 20 percent or more) as a result of implementing the
25 proposed action. Additionally, intersections within the study area along routes
26 chosen as travel time routes were also analyzed. Exhibit 2-2 displays intersections
27 that were analyzed and Exhibit 2-3 shows the intersections that are specifically
28 addressed in this report.

29 **2.5 Transportation Data and Performance Measures**

30 **2.5.1 Sources of Existing Geometric Data and Traffic Control Information**

31 Transportation analysts have previously compiled roadway geometry,
32 channelization, and traffic control (including signal timing) data for the Program.
33 These data were reviewed for consistency with existing field conditions and
34 updated as necessary.

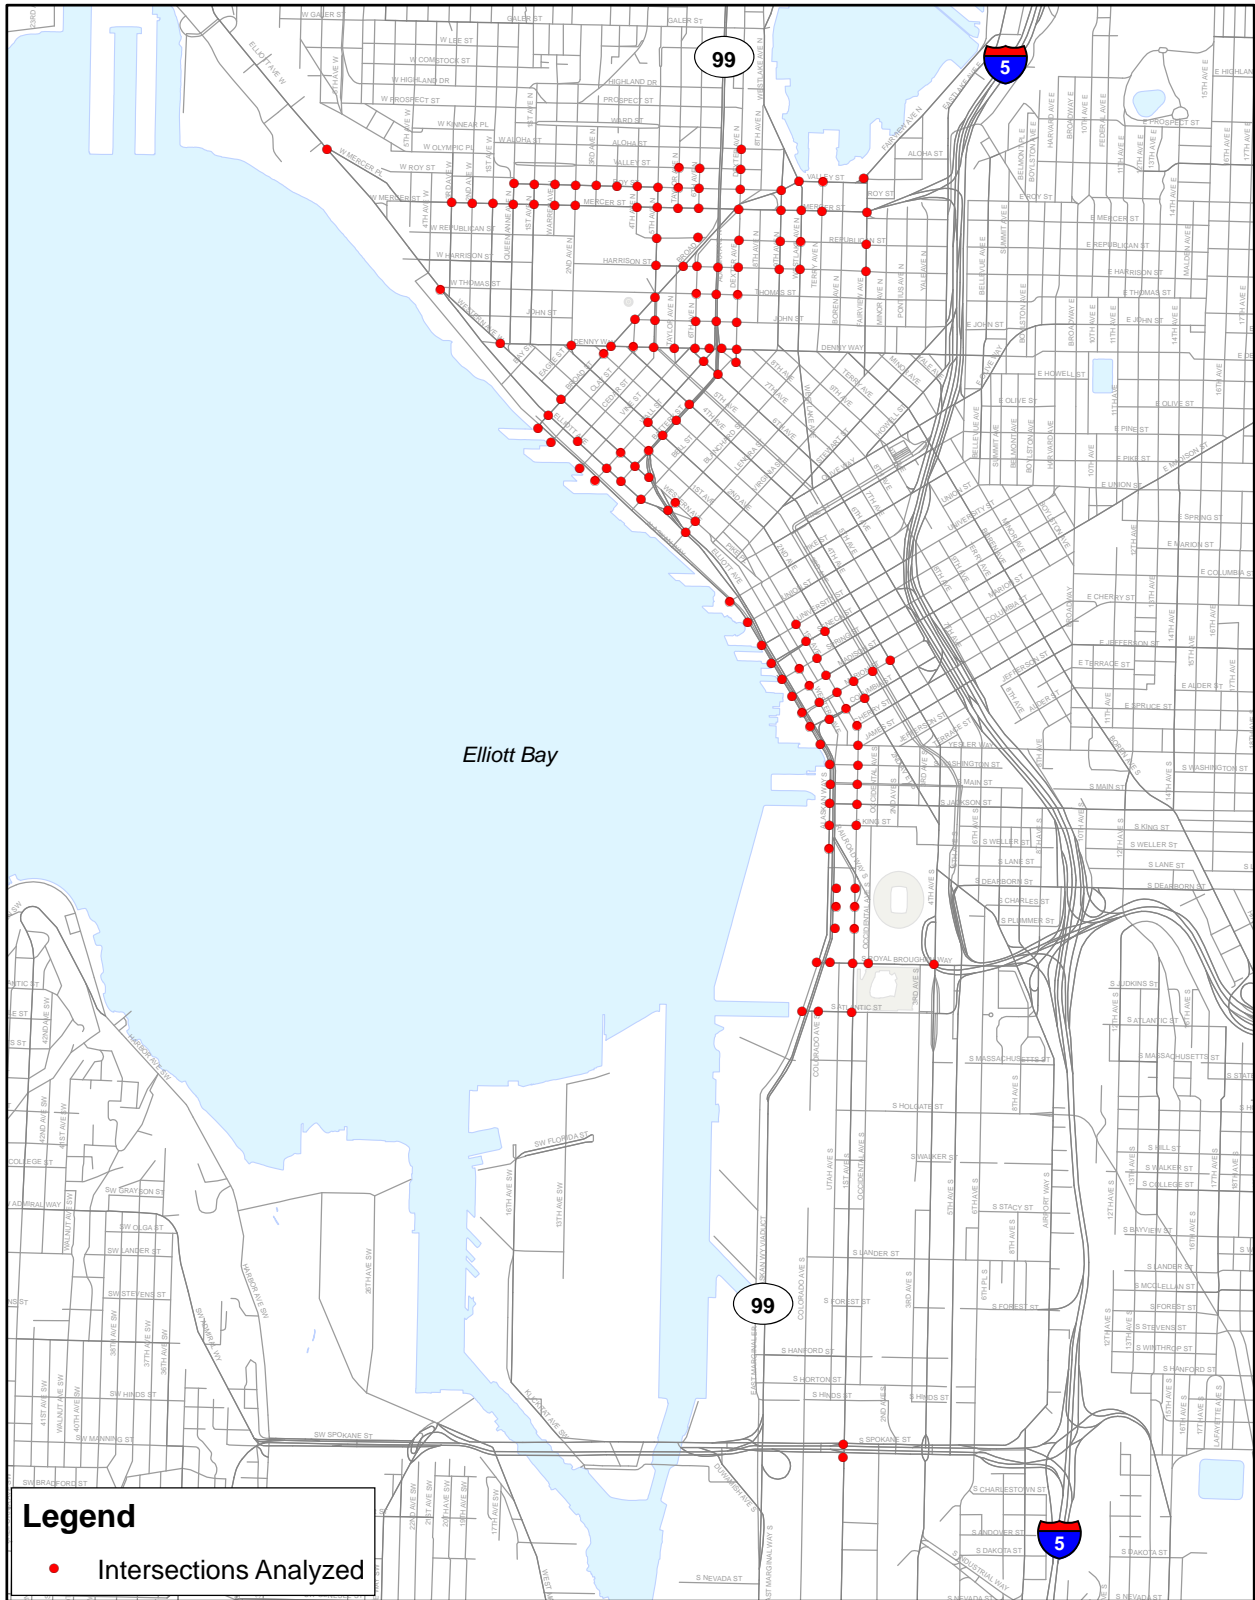

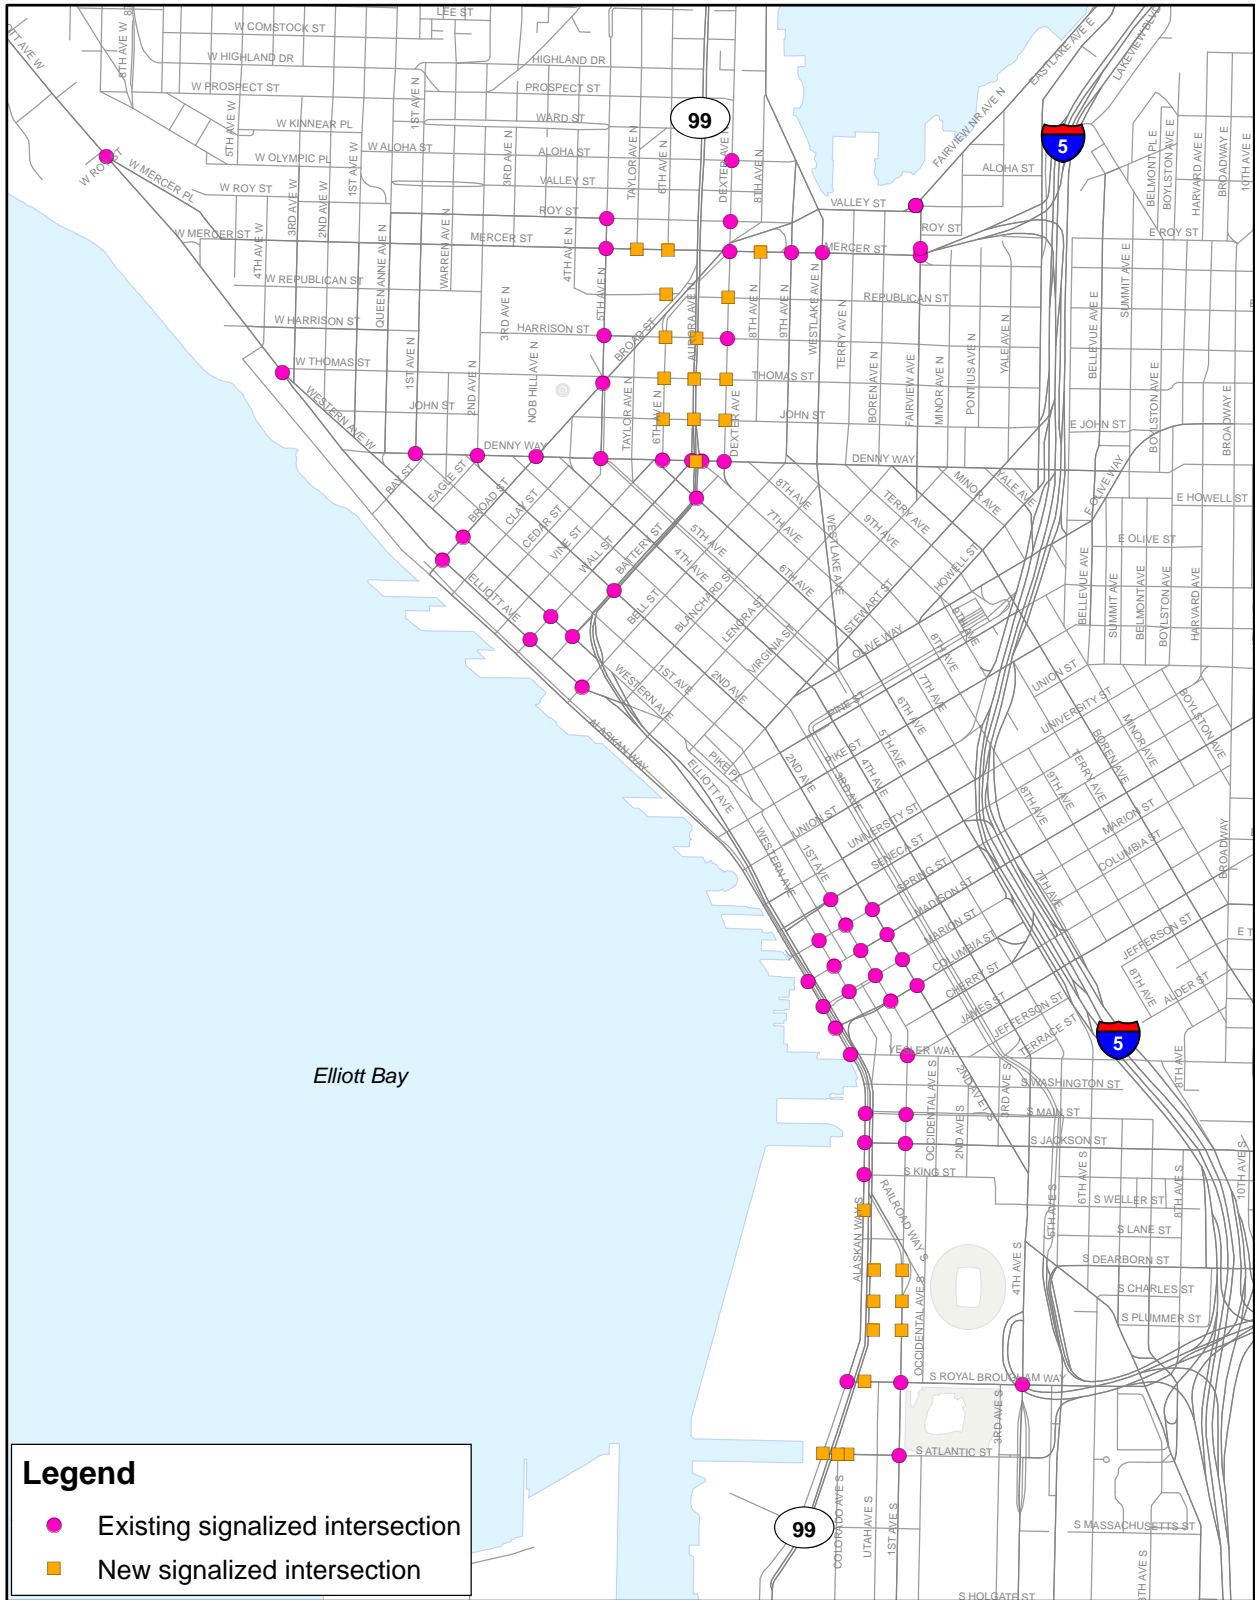

Exhibit 2-2
Intersections Analyzed

**Exhibit 2-3
Intersections Reported**

1 **2.5.2 Traffic Volume Information**

2 **Mainline SR 99 Traffic Counts**

3 Transportation analysts have previously prepared AM peak hour, PM peak hour,
4 and daily traffic volume estimates for SR 99 mainline segments and ramps for
5 2005 conditions. These volume estimates were derived from traffic counts
6 conducted by WSDOT and City of Seattle from 2004 through 2006. Traffic
7 volumes on SR 99 within the study area have generally remained stable in recent
8 years, so these volume estimates may still be considered current. Some additional
9 on-corridor traffic count data were collected in 2007 and 2008 by the City of
10 Seattle. These data were evaluated and existing traffic volume estimates updated
11 as necessary to reflect changes evident in these latest counts.

12 **Intersection Traffic Counts and Related Data**

13 Previous work associated with the Program led to development of a database of
14 turning movement counts for intersections throughout the study area. Data
15 include AM and PM peak hour vehicle turning movements, heavy
16 vehicle percentages, peak-hour factors, and pedestrian crossings for each
17 intersection leg. Counts have been collected for most traffic signal-controlled
18 intersections within the primary study area. Traffic volumes at minor
19 intersections for which counts are not available have been estimated based on
20 counts at adjacent intersections.

21 Turning movement counts were originally conducted between 2003 and 2005,
22 though the database has been updated as newer data become available. The
23 intersections selected for detailed traffic analysis were evaluated to determine
24 whether newer traffic counts were needed. This process involved considering
25 whether new development in the area is likely to have altered traffic patterns
26 since the date the current traffic count was conducted, and comparing turning
27 movement count volumes to newer automated traffic counter data available from
28 the City of Seattle (2007-08). New peak hour turning movement counts were
29 conducted for locations where current estimates are determined to be out of date.
30 Newer counts were compared to prior counts to identify any anomalies.

31 **High-Occupancy Vehicles)**

32 AM and PM peak period vehicle occupancy data were collected for the existing
33 Seneca Street off-ramp and Columbia Street on-ramp. The purpose for focusing
34 on the midtown ramps is to assess high-occupancy vehicle (HOV) usage into/out
35 of downtown to support decisions related to providing transit and/or HOV
36 priority into the CBD from the south. The SR 99 corridor does not presently
37 contain any HOV facilities within the study area.

1 **Nonmotorized Users**

2 Pedestrian volumes at intersections were collected with the arterial turning
3 movement counts described previously. Generally, bicycle traffic is counted as
4 part of the vehicle stream. Discrete counts of bicycle traffic were not conducted.

5 **Trucks**

6 Heavy-vehicle volumes were collected during the arterial turning movement
7 counts described previously. These data were supplemented by video
8 reconnaissance of freight traffic on SR 99 conducted in June 2006. Additional
9 information on heavy trucks' use of the SR 99 corridor is summarized in the
10 project memorandum *Updated SR 99 Truck Volumes* (Parsons Brinckerhoff 2006a).
11 Following the Nisqually earthquake of February 2001, weight restrictions were
12 established to prohibit vehicles over 10,000 pounds from using the two left lanes
13 on each level of the viaduct. These restrictions remain in place today.

14 **2.5.3 Parking Inventory**

15 On-street parking in the Seattle CBD and along the waterfront was counted in
16 2001, with additional counts in 2002 and 2003 and an updated count in 2006.
17 Location and types of parking were rechecked in 2009. Parking spaces
18 surrounding the north portal area were counted in the summer of 2009. City of
19 Seattle parking space data from 2009 also were used. Off-street parking data
20 collected in 2005 and published in 2006 by PSRC have been obtained.

21 **2.5.4 Transit Service Routes and Frequencies**

22 Transit information was collected that related to service coverage, frequency, and
23 travel times for buses that currently use SR 99 and other nearby street segments
24 from published schedules and maps provided by King County Metro,
25 Community Transit, Pierce Transit, and Sound Transit. Available transit
26 ridership data from King County Metro were collected, and modeled transit
27 ridership statistics from the project's travel demand model (see Section 2.3) were
28 used to compare relative levels of ridership.

29 **2.5.5 Ferry Service Characteristics at Colman Dock**

30 Washington State Ferries representatives have previously provided data relating
31 to current ferry vessel capacities, ferry operating schedules, Seattle Ferry
32 Terminal vehicle holding capacity, and typical loading and unloading
33 procedures. Information on street-level pedestrian activity and actual traffic
34 counts in the vicinity of Colman Dock have also been collected, as previously
35 described.

1 **2.5.6 Collision Data for SR 99**

2 A comprehensive evaluation of collision history on the SR 99 corridor was
3 conducted in 2007, reviewing collision data from 2000 through 2003. Additional
4 crash data for the Battery Street Tunnel area were assessed for 2004.
5 Additionally, crash data recently gathered for the corridor for years 2005 through
6 2007 was assessed.

7 **2.6 Analysis of Existing Conditions (Affected Environment)**

8 Existing conditions analysis was conducted for a base year of 2005, unless
9 otherwise noted. The elements of the analysis are described below.

10 **2.6.1 Regional Context and Travel Patterns**

11 The project’s travel forecasting model was used to estimate travel patterns on
12 regional transportation corridors, including I-5, SR 99, and major arterials in
13 central Seattle at screenline locations north, south, and in downtown Seattle.
14 Transit ridership and total person-throughput estimates for all travel modes were
15 prepared at the screenline level. Additionally, projected regionwide AM peak
16 period, PM peak period, and daily vehicle miles of travel (VMT), vehicle hours of
17 travel (VHT), and vehicle hours of delay (VHD) are reported from the travel
18 demand forecasting model, as well as daily transit mode shares to/from the
19 Center City area.

20 **2.6.2 Traffic Operations on SR 99**

21 AM and PM peak hour travel speed and LOS for all mainline segments and
22 ramps on SR 99 are reported. These data were estimated from traffic simulation
23 modeling as described previously. Notable areas of congestion are identified and
24 described.

25 LOS is a measure that characterizes the operating conditions, as perceived by a
26 driver or facility user, of a highway, street, or other transportation facility.
27 Although LOS is a qualitative measure, it is based on quantitative measures, such
28 as traffic density, average speed, or average vehicle delay. A range of six LOS
29 designations, ranging from “A” to “F,” is defined in the HCM. LOS A represents
30 ideal, uncongested operating conditions, while LOS F designates congested,
31 breakdown conditions. LOS B through LOS D designate intermediate operating
32 conditions, while LOS E denotes conditions at the point of maximum service rate.

33 LOS for either freeway segments or multilane highway segments is derived from
34 traffic density and classified according to the ranges shown in Exhibit 2-4. SR 99
35 is best classified as a multilane highway north of Denny Way. South of Denny
36 Way it most closely functions as a freeway, though its posted speed is lower than

1 a typical freeway. Both multilane arterial and freeway classifications use the
 2 same density range to estimate LOS. These traffic density ranges are used to
 3 classify LOS for all SR 99 mainline and ramp segments. However, because
 4 SR 99's posted speeds are less than a typical freeway's, the LOS as based on the
 5 HCM density ranges for freeways will likely be lower than is truly experienced on
 6 the facility. Note that intersection LOS at ramp termini are also categorized using
 7 intersection-based LOS measurements as described in the following section.

8 **Exhibit 2-4. Level of Service Designations for Freeways or Multilane Highways**

LOS (Freeway/Highway Segments)	Density Range (pcpmp)
A	0–11
B	> 11–18
C	> 18–26
D	> 26–35
E	> 35–45
F	> 45

9 pcpmp = passenger car equivalents per mile per lane.

10 Source: Transportation Research Board *Highway Capacity Manual* (2000).

11 **2.6.3 Traffic Operations at Key Arterial Intersections**

12 Average vehicle delay and LOS for AM and PM peak hour conditions for selected
 13 study area intersections on adjacent and nearby arterials are reported.
 14 Additionally, locations with queuing issues are described.

15 Average vehicle delay is reported from either Synchro's HCM Signals report or
 16 from the VISSIM model. Intersection LOS is based on the average delay per
 17 vehicle and is categorized as shown in Exhibit 2-5.

18 **Exhibit 2-5. Level of Service Designations for Signalized Intersections**

LOS (Signalized Intersection)	Average Vehicle Delay (seconds)
A	0–10
B	> 10–20
C	> 20–35
D	> 35–55
E	> 55–80
F	> 80

19 Source: Transportation Research Board *Highway Capacity Manual* (2000).

1 **2.6.4 Roadway Connectivity and Access**

2 SR 99 connections were identified by movement (e.g., southbound SR 99 to Denny
3 Way) and evaluated qualitatively as providing “good access,” “partial or
4 substandard access,” or “no access.” These designations reflect the degree of
5 connectivity provided (full access, partial access, or no access); the quality of
6 connections (high-speed/capacity ramp connections, low-speed/capacity ramp
7 connections, or arterial connections); and the type of connection provided (direct
8 connection, short indirect connection, or longer indirect connection requiring
9 extended arterial travel).

10 **2.6.5 Transit Services**

11 Public transportation services in the study area are described. Those bus routes
12 that could be directly affected by proposed changes to SR 99 under the Bored
13 Tunnel Alternative are identified and described in terms of routing, frequency of
14 service, and scheduled travel times.

15 **2.6.6 Truck Traffic and Freight**

16 Truck volumes on SR 99 were mapped. Major freight generators and destinations
17 were identified, and truck use of SR 99 is described (including current weight and
18 flammable/hazardous materials restrictions).

19 **2.6.7 Parking**

20 The location and type of parking for areas that may be affected by the project are
21 described. Parking utilization is also described in a general sense as allowed by
22 existing data.

23 **2.6.8 Pedestrians**

24 Pedestrian facilities proximate to the corridor are described. Major pedestrian
25 generators and their characteristics are also identified, such as the stadiums, the
26 Seattle Ferry Terminal at Colman Dock, and attractions along the waterfront.
27 Pedestrian activity is quantified for areas where activity is known to be high, with
28 particular emphasis on the waterfront. Pedestrian interactions with vehicle traffic
29 are discussed as related to Alaskan Way, Aurora Avenue, and ramps from the
30 Alaskan Way Viaduct.

31 **2.6.9 Bicycles**

32 Bicycle routes and facilities are identified, and bicycle activity in the study area is
33 generally described.

1 **2.6.10 Ferries**

2 Current ferry operations at the Seattle Ferry Terminal, with emphasis on both
3 pedestrian and vehicle access/egress from the terminal, are described. To capture
4 traffic operating characteristics for the intersections that provide egress from
5 Colman Dock, delay and LOS were calculated separately for periods during
6 which ferry traffic is actively exiting the dock (and signal preemption is ongoing)
7 and periods during which no ferry traffic is exiting the dock.

8 **2.6.11 Collision History**

9 Current high-accident locations and high-accident corridors were identified, and
10 the factors that contribute to the high incidence of collisions at those locations
11 were described. A more detailed discussion of collision history also is presented,
12 updating the prior Program analysis conducted for 2001–03 to reflect the most
13 recent available collision data (2005-07). The following elements are considered:

- 14 • *Collision Rates:* To allow comparison of crash rates between corridor
15 segments and to average rates on similar facilities, collisions per million
16 vehicle miles of travel (MVMT) were calculated for each corridor segment.
- 17 • *Collision Types:* The share of collisions for major crash types (e.g., fixed-
18 object collisions, rear-end collisions) relative to total collisions, and
19 collision rates by type (per MVMT) were reported. Comparing the
20 proportion of accident types by segment can help identify possible
21 contributing factors to collisions.
- 22 • *Collision Severity:* The share of injury collisions (per MVMT) relative to
23 total collisions was reported.

24 **2.7 Analysis of Future Conditions and Environmental Effects**

25 As discussed in Section 2.3.2, the project’s travel demand forecasting model was
26 used to derive estimated changes in travel patterns and traffic volumes for the
27 future years of 2015 and 2030. Project construction is expected to occur between
28 2011 and 2016. Both the construction analysis and year-of-opening analysis rely
29 on model runs for 2015. Detailed analysis was conducted for the baseline (2015),
30 project design year (2015), and project horizon year (2030) conditions.

31 **2.7.1 Conditions in 2015 and 2030**

32 **Changes in Travel Patterns and Systemwide Performance Measures**

33 The travel demand forecasting model was used to estimate how travel patterns
34 might change under the 2015 Baseline, Viaduct Closed (No Build Alternative),
35 and Project conditions, as well as 2030 Project conditions. Traffic volumes on
36 regional transportation corridors, including I-5, SR 99, and major arterials in

1 central Seattle were compared at study area screenline locations north, south, and
2 in downtown Seattle.

3 Transit ridership and total person-throughput estimates (for total vehicles and
4 transit modes) were prepared at the screenline level. Additionally, forecasted
5 regionwide AM peak period, PM peak period, and daily VMT, VHT, and VHD
6 are reported, as well as daily transit mode shares to/from the Center City area.

7 **Traffic Operations on SR 99**

8 AM and PM peak hour travel speeds and LOS for all mainline segments and
9 ramps on SR 99 were developed for 2015 and 2030 scenarios. These data were
10 estimated from VISSIM traffic simulation modeling of the Baseline, Viaduct
11 Closed (No Build Alternative), Project, and Partial Program scenarios. Notable
12 areas of congestion and any substantial difference in operating conditions are
13 identified and described.

14 Travel characteristics on Alaskan Way for the Bored Tunnel Alternative were
15 compared to existing SR 99 trips that use the Elliott/Western Avenue ramps.

16 **Traffic Operations at Key Arterial Intersections**

17 Average vehicle delay, LOS, and queues for AM and PM peak hour conditions for
18 2015 Baseline and Project and 2030 Project were estimated for selected study area
19 intersections, consistent with locations evaluated for existing conditions. Any
20 new or revised intersections under the Bored Tunnel Alternative were included in
21 the evaluation.

22 Intersection analyses were undertaken to calculate estimated vehicle delay by
23 intersection approach for the Viaduct Closed (No Build Alternative) and the
24 Partial Program as needed to provide input to the travel time analyses. Peak hour
25 volumes used for these intersection analyses were developed by applying the
26 implied traffic volume growth/changes indicated by the project's travel demand
27 forecasting model to observed peak hour traffic counts.

28 All intersection analyses were conducted using the Synchro/SimTraffic model
29 version 7.0 for all locations analyzed. Additionally, the VISSIM model version 5.1
30 was used to analyze intersections on the following arterials:

- 31 • Alaskan Way from Broad Street to S. Royal Brougham Way
- 32 • Elliott and Western Avenues from Mercer Place W. to Blanchard Street
- 33 • New Elliott/Western Connector arterial between Elliott/Western Avenues
34 and Alaskan Way surface street (where applicable)
- 35 • Mercer Street from I-5 to Elliott Avenue

1 These VISSIM analyses were conducted for the following four scenarios:

- 2 1. 2015 Baseline (with the existing Alaskan Way Viaduct in place)
- 3 2. 2015 Viaduct Closed (No Build Alternative) (without the existing
- 4 Alaskan Way Viaduct in place)
- 5 3. 2015 Project Build
- 6 4. 2030 Project Build

7 Travel Times

8 AM and PM peak hour travel time estimates for 2015 conditions and the 2030
9 Bored Tunnel Alternative were developed for routes that represent major traffic
10 movements accommodated by the SR 99 corridor. The routes selected extend
11 beyond the traffic study area boundary to better represent the total travel times
12 that actual trips might take. This allows the relative difference in travel times to
13 be considered in context with the total travel times for longer-distance trips, i.e.,
14 those originating or destined to locations outside the study area.

15 Travel time estimates were generated from models. Within the study area, travel
16 time estimates for SR 99 segments and ramps were derived from VISSIM
17 simulation model results. For arterial segments, travel time estimates were based
18 on free-flow speeds and intersection delay estimated from VISSIM simulation
19 model results where available, and/or Synchro operations analysis results as
20 available. Finally, the travel demand model travel speeds were used as a basis for
21 calculating travel times along route segments outside of the study area (e.g., SR 99
22 north of Aloha Street, 15th Avenue W. north of Elliott Avenue, and the West
23 Seattle Bridge west of Harbor Island). Additionally, travel time contours were
24 estimated from the travel demand model and presented graphically for each
25 alternative.

26 Travel times are reported for each direction of travel on routes that represent the
27 following range of trips covering all of the affected corridor segments:

- 28 • South to/from downtown, represented by West Seattle to CBD via SR 99.
- 29 • North to/from downtown via SR 99, represented by Woodland Park
- 30 (SR 99 and N. 50th Street) to CBD.
- 31 • Through trips on SR 99, represented by Woodland Park to Spokane Street.
- 32 • Through trips on the Elliott/Western corridors, represented by Ballard
- 33 Bridge to Spokane Street.
 - 34 a. via Alaskan Way (or AWW if applicable)
 - 35 b. via Mercer Street and the bored tunnel

- 1 • Mercer Street: from I-5 to Elliott Avenue
 - 2 • Northgate to Boeing Access Road via I-5
- 3 Travel times for all routes were not estimated for every alternative and future
 4 year. Exhibit 2-6 identifies which travel time estimates were developed for each
 5 scenario analyzed, including for existing conditions.

6 **Exhibit 2-6. Scenarios and Routes for Estimated Travel Times**

Routes	Year 2015			2030	
	Existing ¹	Baseline	Viaduct Closed	Project	Project
West Seattle Jct. to CBD (Seneca Street & Fourth Avenue) via SR 99, Alaskan Way		Peak direction only		Peak direction only	Peak direction only
Woodland Park (SR 99 & N. 50th Street) to CBD		Peak direction only		Peak direction only	Peak direction only
Woodland Park (SR 99 & N. 50th Street) to Spokane Street	PM peak only	AM & PM	AM & PM	AM & PM	AM & PM
Ballard Bridge/Elliott to Spokane Street					
A) via Alaskan Way (or AWV if applicable)	PM peak only	AM & PM		AM & PM	AM & PM
B) via Mercer Street, bored tunnel				AM & PM	AM & PM
Northgate to Boeing Access Road via I-5		AM & PM		AM & PM	AM & PM
Mercer Street: I-5 to Elliott		AM & PM		AM & PM	AM & PM

7

8 **Roadway Connectivity and Access**

9 The Bored Tunnel Alternative’s connections were identified by movement (e.g.,
 10 southbound SR 99 to Denny Way) and evaluated qualitatively as providing “good
 11 access,” “partial or substandard access,” or “no access.” These designations
 12 reflect the degree of connectivity provided (full access, partial access, or no
 13 access); the quality of connections (high-speed/capacity ramp connections, low-
 14 speed/capacity ramp connections, or arterial connections); and the type of
 15 connection provided (direct connection, short indirect connection, or longer
 16 indirect connection requiring extended arterial travel).

17 **Transit**

18 The expected effects on transit services were assessed using both qualitative and
 19 quantitative information. Expected changes in transit routing under the project
 20 are identified and compared to routing under baseline conditions. The
 21 comparison focuses on changes in coverage area and potential effects on speed

1 and reliability (based on traffic operations results). Traffic analysis results are
2 used to gauge potential travel time effects on routes operating on SR 99 (Aurora
3 Avenue and SODO). Modeled changes in mode share are reported as well.

4 **Truck Traffic and Freight**

5 The project's effects on freight and goods movement, including comparison of
6 routing alternatives for trips that currently use the Elliott/Western Avenue
7 corridor, are described, along with potential changes in vehicle restrictions
8 (regarding weight and/or flammable or hazardous materials).

9 **Parking**

10 Potential parking effects are quantified for the area that would be directly affected
11 by the project. The location and proximity to dependent uses and alternative
12 parking availability also are qualitatively examined.

13 **Pedestrians**

14 Pedestrian components of the project are described in addition to other project-
15 related changes that could affect the quality and/or safety of pedestrian facilities.
16 In particular, potential effects associated with changes to Alaskan Way, Aurora
17 Avenue, and SR 99 ramp locations were examined to gauge pedestrian exposure
18 to vehicle traffic, effects to pedestrian connectivity, and means for providing safe
19 and convenient crossings of streets and highways.

20 **Bicycles**

21 Bicycle facility components of the project are characterized, as well as other
22 project-related changes that could affect the quality and/or safety of bicycle travel.
23 The assessment considers how changes in roadway configuration and traffic
24 volumes on Alaskan Way might affect bicycling there.

25 **Ferry Traffic**

26 Changes in vehicle access and egress from the Seattle Ferry Terminal at Colman
27 Dock are described and compared to baseline conditions.

28 **Event Traffic**

29 Traffic conditions and access to major events in the stadium area and at Seattle
30 Center are described qualitatively, taking into consideration normal peak hour
31 traffic conditions, changes in traffic patterns and volumes associated with events,
32 and event-related pedestrian activity.

33 **Safety**

34 Potential changes in conditions that could affect motorist, pedestrian, and vehicle
35 safety are assessed based on review of the major design elements associated with

1 the project, including facility type, lane widths, geometric configuration, and
2 potential vehicle and pedestrian conflict locations. The safety discussion also
3 assesses how design features might affect existing locations that experience a
4 relatively higher share of accidents, or potentially introduce new or different
5 safety issues.

6 2.7.2 Conditions in 2040

7 A “high-level” year 2040 assessment was conducted by analyzing projected
8 population and employment growth both in the region and in the Center City
9 area. Based on this, a qualitative discussion of the potential effect of year 2040
10 conditions on the project’s operational performance is included.

11 2.7.3 Construction Travel Conditions

12 Traffic management approaches (detours) associated with major construction
13 stages are described. Travel forecasts were prepared for one construction stage,
14 corresponding to the stage that is expected to be most disruptive. SR 99 mainline
15 speeds and travel times are estimated. Travel disruption during other
16 construction stages is described qualitatively relative to this modeled stage.
17 Transportation measures to help maintain mobility and access during
18 construction are suggested based on the degree, location, and extent of disruption
19 forecast. Impacts to stadium and Seattle Center event access and egress is
20 assessed and discussed qualitatively.

21 2.8 Cumulative Effects

22 Cumulative effects are those that, when combined with the effects of past,
23 present, and reasonably foreseeable neighboring projects, may have an additive
24 effect on the environment. The focus of the cumulative effects analysis is on the
25 combined effect of the project (proposed action), Program elements, and other
26 projects that are anticipated to add to transportation effects in the study area.
27 Two levels of cumulative effects were assessed. The first level includes the
28 project plus Program elements. This level is assessed quantitatively. The second
29 level of cumulative effects includes all Program elements plus other regional
30 transportation projects. This analysis is qualitative in nature and relies on other
31 studies previously conducted.

32 2.8.1 Program Elements

33 Other roadway Program elements were assessed for operational and construction
34 effects using the available design year (2015) and horizon year (2030) traffic data
35 and potential roadway alignments. The projects included in this analysis include
36 the following:

- 1 • Alaskan Way Surface Street Improvements
- 2 • Elliott/Western Connector
- 3 • Mercer Street West Corridor Improvements
- 4 • First Avenue Streetcar
- 5 • Transit Enhancements
- 6 • Northbound and southbound right-side transit lanes on SR 99 from just
- 7 south of the Aurora Bridge to north of Aloha Street

8 Non-roadway/transit elements of the Program are qualitatively evaluated:

- 9 • Seawall Replacement
- 10 • Alaskan Way Promenade

11 2.8.2 Other Projects

12 Other projects include the following major projects (some of which are already
13 included in the project baseline):

- 14 • Cumulative effects specifically associated with major construction projects
15 in or near downtown Seattle
 - 16 • Bridging the Gap Projects
 - 17 • Sound Transit University Link light rail - Extension to University
18 of Washington
 - 19 • Mercer Street two-way conversion from I-5 ramps to Dexter
20 Avenue
 - 21 • North Parking Lot Development at Qwest Field
 - 22 • Bill and Melinda Gates Foundation Campus
 - 23 • E. Marginal Way Grade Separation
 - 24 • S. Spokane Street Widening
- 25 • Other planned transportation projects with potential cumulative effects
 - 26 • I-5 Improvements
 - 27 • SR 520 Project
 - 28 • I-405 Improvements
 - 29 • I-90 Improvements
 - 30 • SR 509 Improvements
 - 31 • South Lake Union and/or South Downtown redevelopment

32 Potential changes in travel effects associated with the combined or cumulative
33 implementation of the identified projects are qualitatively described for both
34 construction and operational timeframes. Other subject areas also describe
35 related cumulative effects in their discipline reports (e.g., any potential for
36 induced growth would be described in the Land Use Discipline Report).

1 **2.8.3 Changes in Travel Patterns and Systemwide Performance Measures**

2 The travel demand forecasting model was used to estimate how travel patterns
3 might change under 2015 Partial Program and full Program, and 2030 Program
4 conditions. The same performance measures as outlined in Section 2.7.1 above
5 are assessed for cumulative effects.

6 **2.8.4 Traffic Operations on SR 99**

7 AM and PM peak hour travel speeds and LOS were calculated for all mainline
8 segments and ramps on SR 99 for the 2015 Partial Program. These data were
9 estimated from VISSIM traffic simulation modeling. Notable areas of congestion
10 and any substantial difference in operating conditions are identified and
11 described. Travel characteristics on Alaskan Way under the Program scenario are
12 specifically compared to existing SR 99 trips that use the Elliott/Western Avenue
13 ramps.

14 **2.8.5 Traffic Operations at Key Arterial Intersections**

15 AM and PM peak hour vehicle delay by approach for key study area arterial
16 intersections for the 2015 Partial Program and 2030 Program were developed, as
17 needed, to provide input to the travel time analyses.

18 Intersection analyses were conducted using the Synchro/SimTraffic model
19 software Version 7.0. Additionally, the VISSIM model version 5.1 was used to
20 analyze intersections on the following arterials:

- 21 • Alaskan Way from Broad Street to S. Royal Brougham Way
- 22 • Elliott and Western Avenues from Mercer Place W. to Blanchard Street
- 23 • New Elliott/Western Connector arterial between Elliott/Western Avenues
24 and Alaskan Way surface street (where applicable)
- 25 • Mercer Street from I-5 to Elliott Avenue

26 **2.8.6 Travel Times**

27 AM and PM peak hour travel time estimates were developed for the cumulative
28 effects scenarios as indicated in Exhibit 2-7 consistent with the methodology
29 identified previously. Exhibit 2-8 shows the routes graphically.

1 **Exhibit 2-7. Scenarios and Routes for Estimated Travel Times for Cumulative Effects**

Routes	2015 Partial Program	2030 Full Program
West Seattle Jct. to CBD (Seneca Street & Fourth Avenue) via SR 99, Alaskan Way	Peak direction only	
Woodland Park (SR 99 & N. 50th Street) to CBD	Peak direction only	
Woodland Park (SR 99 & N. 50th Street) to Spokane Street	AM & PM	
Ballard Bridge/Elliott to Spokane Street		
A) via Alaskan Way (or AWV if applicable)	AM & PM	AM & PM
B) via Mercer Street, bored tunnel	AM & PM	AM & PM
Northgate to Boeing Access Road via I-5	AM & PM	
Mercer Street: I-5 to Elliott	AM & PM	AM & PM

2

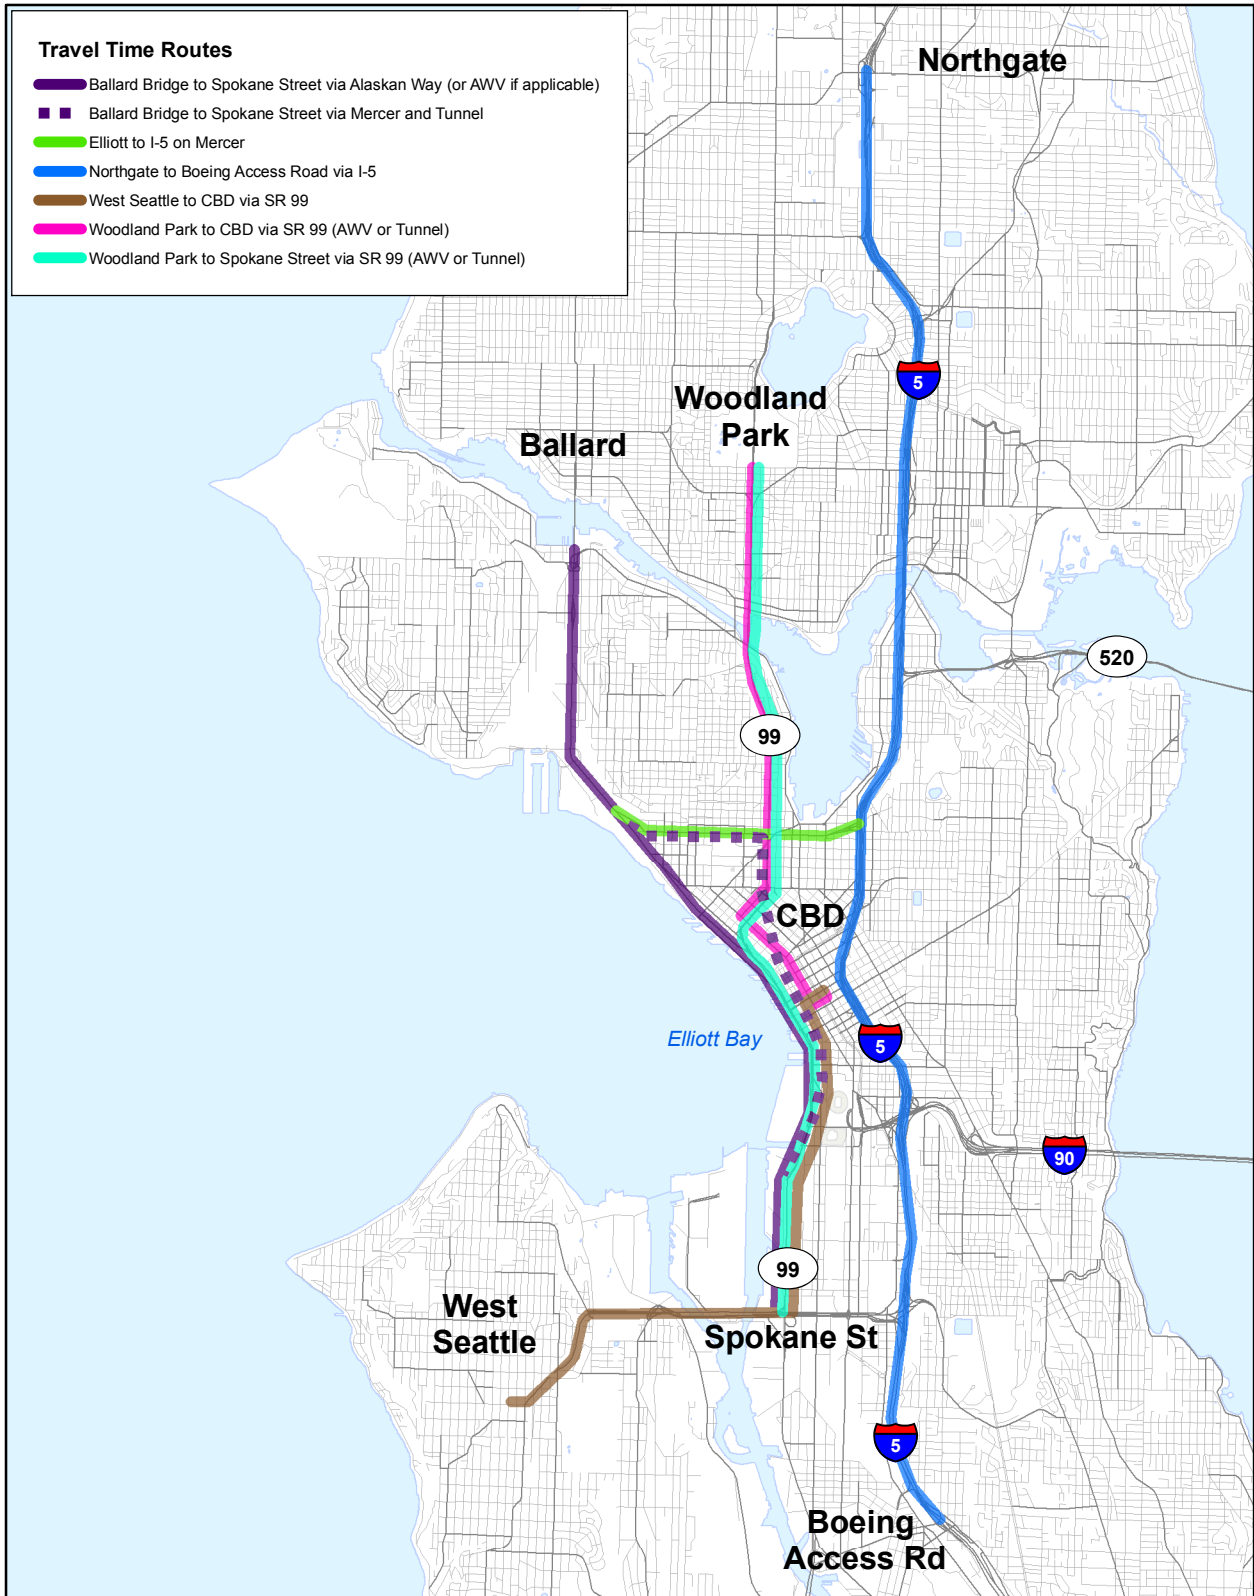

3 **2.9 Determining Transportation Mitigation Measures**

4 **2.9.1 Operational Mitigation**

5 Long-term (post-construction) transportation mitigation measures are not
6 anticipated for the project.

7 **2.9.2 Mitigation of Adverse Effects on Travel During Construction**

8 A program of measures to help maintain mobility and access during construction
9 is recommended based on proposed detour routes and the forecast degree of
10 travel disruption, including changes in existing pedestrian or vehicle circulation
11 patterns, parking, and changes in access. The measures build on efforts
12 completed previously for the Program’s Draft Construction Transportation
13 Management Plan (Parsons Brinckerhoff 2006b). The intent of the mobility
14 measures is to maximize the throughput of available routes; preserve access to
15 businesses, public facilities, and residences; maintain truck and Port drayage
16 routes; and protect the reliability of transit services during the construction
17 period.

Chapter 3 STUDIES AND COORDINATION

This section provides a summary of the studies and adopted plans undertaken in the region that have relevance to this project. Also included is a summary of coordination activities undertaken to guide the development of traffic and transportation components of the project.

3.1 Relevant Studies and Plans

3.1.1 City of Seattle Comprehensive Plan (2005)

The City of Seattle's Comprehensive Plan, *Toward a Sustainable Seattle*, articulates a vision of how Seattle will grow in ways that sustain its citizens' values. The City first adopted the Comprehensive Plan in 1994 in response to the state Growth Management Act of 1990. Multimodal transportation policies discussed in the Comprehensive Plan were used to define the project's system elements. In particular, transportation demand policies and system management strategies were used to guide development of the project's mitigation plans.

3.1.2 City of Seattle Transportation Strategic Plan (2005)

The *Transportation Strategic Plan* describes SDOT's vision, goals, and policies for achieving the City's long-range objectives. It describes the actions, projects, and programs that SDOT will take to promote economic growth in Seattle and the region, support livable neighborhoods, improve the environment, and address the traveling public's complex demands. Information from this plan was used to help refine the project's travel demand models.

3.1.3 City of Seattle Bicycle Master Plan (2007)

The *Seattle Bicycle Master Plan* is a planning document used to guide future improvements to Seattle's bicycle network. This master plan focuses on evaluating arterial streets to implement bike lanes and encourage more bicycling throughout the city of Seattle.

3.1.4 City of Seattle Center City Circulation Report (2003)

The City of Seattle conducted a study of transit and nonmotorized circulation and service options in the downtown area. This study is an effort to better integrate numerous independent transportation components and plans in the downtown area.

1 **3.1.5 City of Seattle Center City Access Strategy (2007)**

2 In preparation for construction and growth, including the project and Program,
3 SDOT is planning, building, and monitoring the implementation of projects in the
4 city center. This strategy involves creating a livable and walkable city center,
5 integrating and simplifying the transit system, accommodating anticipated
6 growth, maintaining access into downtown during major construction projects,
7 and continuing mobility into the future.

8 **3.1.6 City of Seattle Freight Mobility Strategic Action Plan (2005 Plan Update)**

9 The *Freight Mobility Strategic Action Plan* presents a list of actions that SDOT will
10 implement. These actions or tasks address administrative and functional actions
11 that SDOT will carry out to benefit freight, in accordance with the Seattle
12 Comprehensive Plan and the Seattle *Transportation Strategic Plan*. Actions include
13 railroad grade separations, truck guide signing, street improvements, and
14 ongoing communication with the Seattle freight community via the Seattle
15 Freight Mobility Advisory Committee.

16 **3.1.7 Seattle Intermediate Capacity Transit Study (2001)**

17 The *Seattle Transit Study for Intermediate Capacity Transit* examined a wide range of
18 transit technologies and services that offer higher passenger carrying capacity and
19 greater reliability than buses operating in mixed traffic. It included an assessment
20 of the following transit services:

- 21 1. Bus Rapid Transit (BRT) – buses that move quickly and reliably because of
22 improvements such as transit-only lanes or transit priority technology,
23 which gives buses a green light at intersections.
- 24 2. Streetcars and Trams – electric vehicles running on rails in the streets.
- 25 3. Elevated Transit (like monorail) – electric vehicles that are grade-
26 separated or operate in exclusive rights-of-way, allowing them to avoid
27 traffic congestion and other barriers.

28 The intermediate-capacity transit study examined transit system performance for
29 various types of transit service that may operate in the AWV corridor.

30 **3.1.8 City of Seattle Transit Plan (2005)**

31 The City of Seattle adopted a Transit Plan to define its transit strategies for its
32 *Transportation Strategic Plan*. The Transit Plan’s purpose is to provide sound
33 direction on how Seattle can achieve the transit system it needs to meet long-term
34 growth, economic, and transportation objectives for connecting downtown and
35 the emerging set of urban villages. Information from the plan was used to help
36 refine travel networks within the Program’s travel demand models.

1 **3.1.9 Seattle Streetcar Network Development Report (2008)**

2 The City Council approved a Seattle Streetcar Network Concept in early 2008 and
3 authorized SDOT to evaluate the concept and identify the most promising routes
4 for early implementation. The report evaluated a number of potential corridors
5 and routes, including the First Avenue streetcar line that is part of the Program.

6 **3.1.10 Center City Parking Program Work Plan (2008)**

7 The Center City Parking Program is SDOT's effort to address anticipated changes
8 to on-street parking in the Center City over the next several years. This would be
9 accomplished with new marketing, way-finding, and technology measures in place
10 by 2012. The program goal is to provide easy-to-access off-street short-term
11 parking with easy-to-understand pricing that keeps the Center City moving and
12 contributes to a sustainable transportation system.

13 **3.1.11 Waterfront Parking Strategy Study (2002)**

14 The Waterfront Parking Strategy Study was developed through a partnership
15 between the City of Seattle Strategic Planning Office, the Seattle Aquarium, the
16 Metropolitan Improvement District, the Pike Place Market Preservation &
17 Development Authority, and the Port of Seattle. It was commissioned to develop a
18 parking strategy to meet changing needs brought about by new and emerging land
19 uses along the Seattle central waterfront area. The purpose of the strategy was to
20 help the City balance the access and parking needs of a revitalized waterfront with
21 preservation of neighborhood character and businesses.

22 **3.1.12 South Lake Union Transportation Study (Final Report, July 2004)**

23 The main objective of the South Lake Union Transportation Study is to form a set
24 of transportation strategies to address existing problems and to support and shape
25 the development of the South Lake Union Urban Village.

26 **3.1.13 Destination 2030 Metropolitan Transportation Plan**

27 The *Destination 2030* Metropolitan Transportation Plan (MTP) is the adopted
28 regional long-range transportation plan for the central Puget Sound region. The
29 MTP comprises all transportation projects and programs planned for
30 implementation by 2030 (funded and unfunded). The MTP also describes land use
31 and socioeconomic conditions forecasted for 2030, which form the basis for PSRC's
32 travel demand models (the project's travel demand model, as described in Chapter
33 2, is an enhanced version of the PSRC model).

34 The MTP describes the regional transportation system's performance, given
35 implementation of the full complement of projects identified in the plan. It

1 illustrates the cumulative effects of implementing all of the transportation projects
2 and programs planned throughout the region. Conversely, the analysis conducted
3 for the project's Supplemental Draft EIS presumes only those projects that have
4 secured funding and are presently programmed for implementation by 2030.

5 **3.1.14 Sound Transit 2 Plan (2008)**

6 In 2008, voters approved funding for the ST2 Plan, which identified a major
7 expansion of regional transit services. This program includes extensions of the
8 Link light rail transit (LRT) system by 36 miles, a new streetcar line connecting to
9 downtown Seattle, and significant expansion of Sounder commuter rail and
10 ST Express bus service.

11 Currently operating between downtown Seattle and Tukwila (with expansion to
12 the Seattle-Tacoma International [Sea-Tac] Airport scheduled for December 2009),
13 Link LRT under ST2 will be extended to Lynnwood in the north, Overlake in the
14 east, and Federal Way in the south. A new streetcar line will connect Union
15 Station in the south end of downtown Seattle with Capitol Hill. Sounder
16 commuter rail serving downtown Seattle will be enhanced through expanded
17 operations, extended platforms at stations, and improved access at South King and
18 Pierce County stations. ST Express bus service will undergo expansion, including
19 BRT service along the SR 520 corridor.

20 ST2 builds on the initial program of regional service development known as *Sound*
21 *Move*. One of the major elements of Sound Move is construction of LRT to serve
22 the University District. This element, which is currently under construction, is
23 scheduled for completion in 2016. Once complete, LRT service will be provided
24 between downtown Seattle and the University of Washington campus (near Husky
25 Stadium) via Capitol Hill.

26 The transit investments approved in ST2 are included as part of the baseline
27 definition as well as future conditions.

28 **3.1.15 King County Transit Now (2006)**

29 The Transit Now initiative to expand King County Metro bus transit service by
30 15 to 20 percent over the next 10 years was approved by King County voters in the
31 general election on November 7, 2006 (King County Ordinance 2006-0285).
32 Elements of Transit Now are expected to supplement the strategies identified
33 through the project's construction transportation planning process. Travelers to
34 downtown Seattle will benefit from Transit Now both during and after project
35 construction.

36 RapidRide is a key feature of Transit Now and will consist of five corridors with
37 streamlined bus service. Each corridor will have frequent transit operations that

1 include peak period service with headways of 10 minutes or better. Three
2 RapidRide corridors will directly serve downtown Seattle, including portions of
3 the project. These corridors and their estimated years of service inauguration are
4 as follows:

5 C – West Seattle (2011)

6 D – Ballard/Uptown (2012)

7 E – Shoreline via Aurora Avenue (2013)

8 **3.1.16 King County Metro 6-Year Transit Development Plan (2004)**

9 The King County Metro *Six-Year Transit Development Plan for 2002 to 2007* provides
10 the framework for transit service and capital investments. This plan guided transit
11 development for 2002 through 2007. The 6-year transit plan was used to determine
12 annual transit service growth for the regional travel demand models, including Metro
13 bus service and transportation demand management strategies provided by King
14 County Metro. In November 2007, the *Strategic Plan for Public Transportation, 2007-*
15 *2016* replaced and updated the *Six-Year Transit Development Plan*.

16 **3.1.17 King County Ferry District – Technical Studies (2009)**

17 The King County Ferry District is assessing the feasibility of adding new routes to
18 its system. The *King County Ferry District Demonstration Project Technical Studies*
19 *Implementation/Refined Corridor Analysis* (King County 2009) documented the
20 assessment of several potential new ferry routes, including those connecting to
21 downtown Seattle. The analysis identified a short list of four routes for potential
22 implementation in 2010. The routes include Ballard (Shilshole) to downtown
23 Seattle (Pier 50) and Des Moines to downtown Seattle. Further assessment of
24 potential new ferry corridors will take place in 2009 with selection of two finalists
25 by fall of 2009.

26 **3.1.18 Evaluation of Joint Operations in the Downtown Seattle Transit Tunnel (2001)**

27 This joint Sound Transit/King County study issued in August 2001 examined the
28 impact of removing Downtown Seattle Transit Tunnel buses during the planned
29 conversion of the Downtown Seattle Transit Tunnel to joint bus/light rail
30 operations. Of particular note was the impact to downtown streets of distributing
31 tunnel buses to the downtown Seattle arterials for 2 years.

32 **3.1.19 King County Metro Transit Tunnel Conversion Project Performance Reports** 33 **(2005–2007)**

34 King County Metro, under the “Agreement Regarding the Design, Construction
35 and Operation of the Downtown Seattle Transit Tunnel and Related Facilities,”

1 was mandated to provide periodic reports on the performance of the downtown
2 transportation system during the closure of the Downtown Transit Tunnel
3 Conversion Project. These reports have provided updates on a number of
4 performance measures during the closure of the Downtown Seattle Transit Tunnel.
5 The information in these studies has been helpful in the documentation of
6 potential traffic impacts during construction.

7 3.1.20 Alaskan Way Viaduct Project: Task 1 Report (December 1996)

8 The Task 1 Report provides insights on travel characteristics of trips made on the
9 Alaskan Way Viaduct. The report led to four distinct approaches (Framework
10 Policies) for seeking a course of action. Information from the report provided
11 comparison information for the development of travel forecasts and traffic analysis
12 activities.

13 3.1.21 Washington State Transportation Plan 2007–2026 (November 2006)

14 *The Washington State Transportation Plan 2007–2026* identifies needs and deficiencies
15 of the state’s transportation system, including designated state highways. The
16 plan was the result of a continuous, comprehensive, and coordinated planning and
17 outreach effort with other agencies and the public to identify potential
18 transportation improvements.

19 3.2 Coordination

20 FHWA, WSDOT, and City of Seattle are lead agencies for this study. Cooperating
21 agencies include the U.S. Army Corps of Engineers, Federal Transit
22 Administration, King County, and the Port of Seattle.

23 Ongoing coordination has been conducted as needed with agencies that manage
24 operations or have a stake in particular transportation modes. This includes:

- 25 • City of Seattle planning, design, and operations staff for multimodal
26 design and operations input.
- 27 • King County Metro staff for transit service and transit capital planning.
- 28 • The Port of Seattle and BNSF for freight and rail operations.
- 29 • Washington State Ferries for vehicle and pedestrian access issues to and
30 from the Seattle Ferry Terminal.

31 In addition, there has been coordination with major stakeholders, including the
32 stadiums, Seattle Center, the freight community, and BNSF Railway and Union
33 Pacific Railroad (UPRR).

Chapter 4 AFFECTED ENVIRONMENT

This chapter describes existing conditions (2005 analysis year) for transportation systems within the study area. Information regarding current transportation facilities, their use, and their performance is presented. This information establishes an understanding of current conditions and serves as a basis against which projected future conditions for the Bored Tunnel Alternative can be compared. Note that while 2005 is listed as the analysis year, existing conditions as reported in this document have been updated where appropriate to reflect more current conditions. This includes changes in transportation facilities and services since 2005 (e.g., roadways, transit, parking supply), and changes in traffic volumes where appropriate. In many cases, 2005 traffic volumes were found to be higher than 2008 volumes due to the recent economic downturn. To reflect more conservative existing conditions, 2005 volumes were retained in those instances.

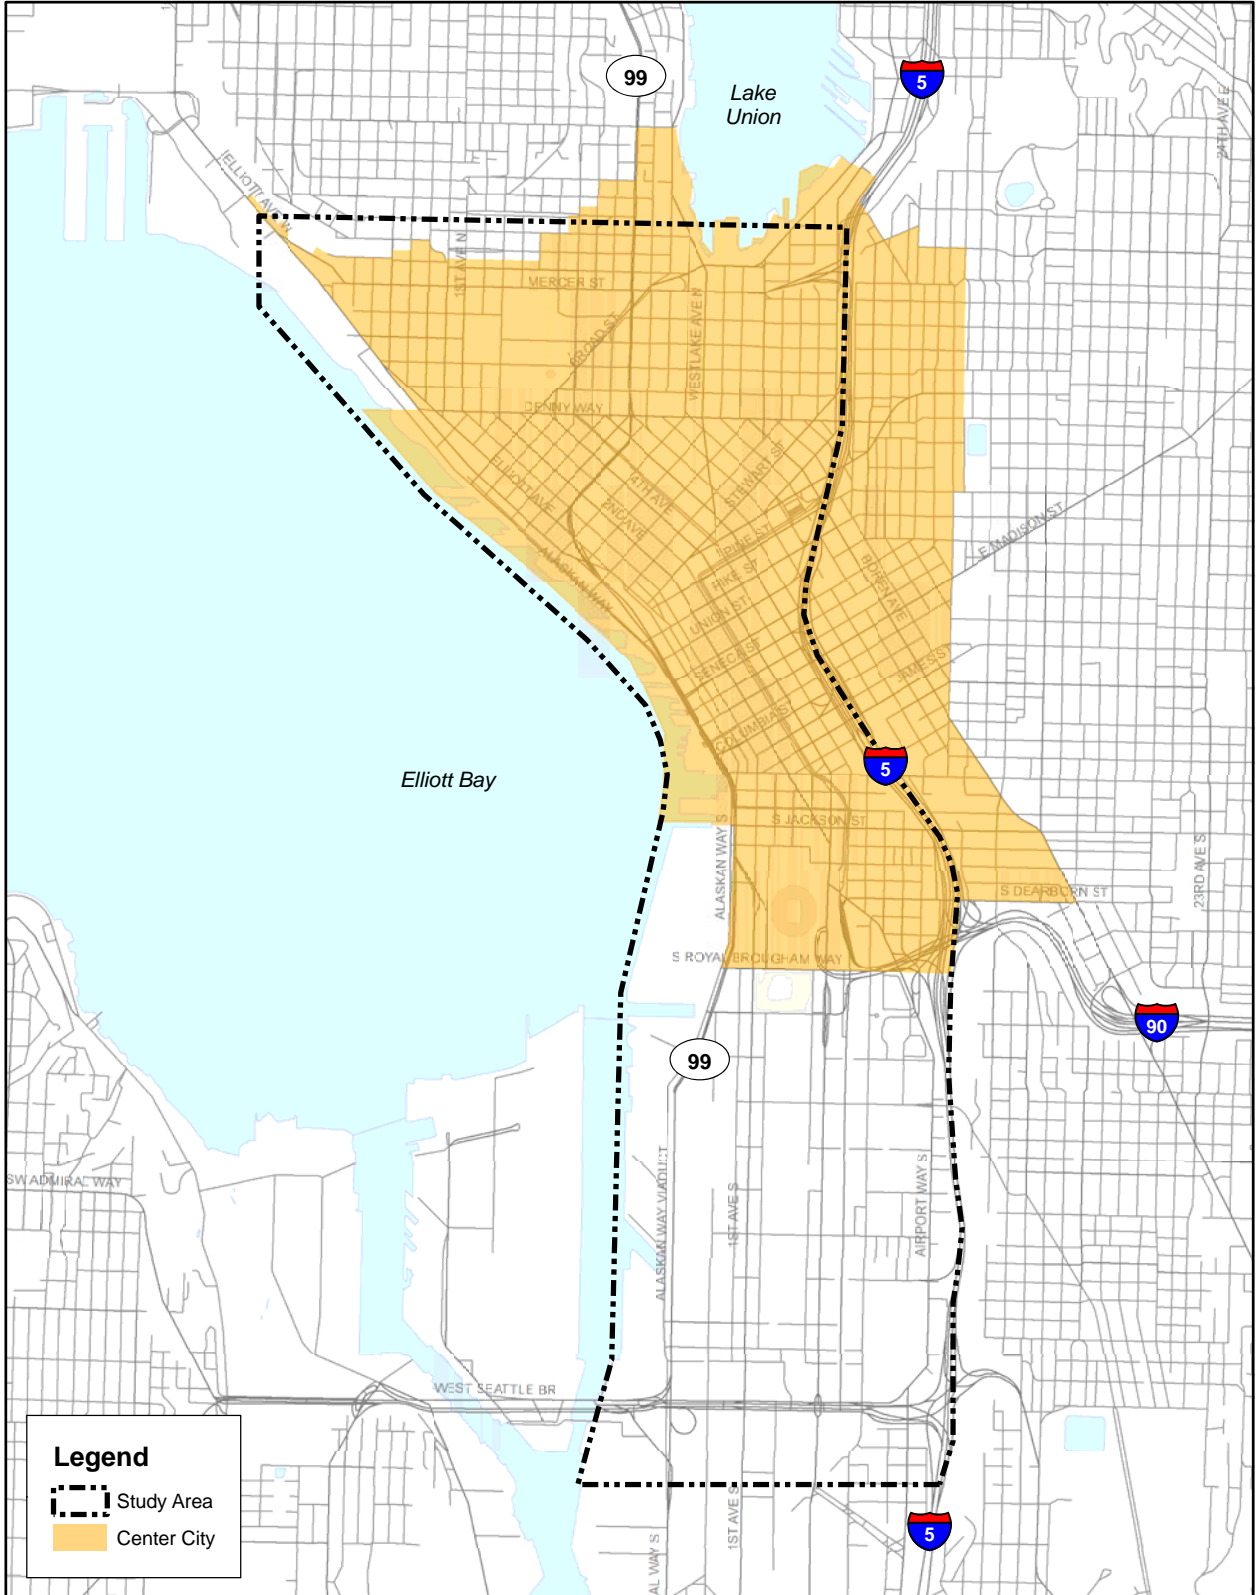

4.1 Regional Context and Travel Patterns

The project is proposing a Bored Tunnel Alternative for the SR 99 corridor through downtown Seattle. The project limits extend from S. Atlantic Street in the south to Roy Street in the north.

A transportation study area, which encompasses the project limits on SR 99, as well as nearby transportation facilities that are closely related to or affected by the SR 99 corridor, was shown in Exhibit 2-1. The study area is roughly bordered by I-5 to the east, Puget Sound to the west, Valley Street in the north, and S. Spokane Street in the south. It includes a range of multimodal transportation facilities and service types, including limited-access highways, arterial streets, HOV facilities, transit services and facilities, ferry services and facilities, nonmotorized facilities and routes, and important freight corridors.

The transportation study area is located within downtown Seattle, a dense urban area that contains a major interstate freeway (I-5), two state routes (SR 99 and SR 519), arterial streets (primary, minor, and collector), and local streets. I-5 is a major state and regional facility and carries the majority of regional traffic through the study area, as well as considerable local traffic. The Seattle Center City is also a useful area for reference. Center City represents the core of Seattle, in terms of geography, jobs, and density. Center City is shown in relation to the study area in Exhibit 4-1.

U:\GIS\le-3\Maps\SDE\IS2-Bored_Tunnell\Center_City.mxd

Data Source: City of Seattle, 2009.

Exhibit 4-1 Center City

1 The transportation study area establishes the area for which the transportation
2 performance and impacts of the Bored Tunnel Alternative are assessed. The most
3 intensive evaluation of transportation performance and impacts is performed on
4 SR 99 itself. Elsewhere in the study area, assessment focuses on capturing the
5 important impacts and primary operational differences associated with the
6 different analysis scenarios. On occasion, information beyond the study area
7 boundaries is provided to provide context for the data being presented.

8 4.1.1 SR 99

9 SR 99 serves important local and regional transportation functions. Within the
10 project area, it provides access to downtown for many parts of the western
11 neighborhoods of the city of Seattle and provides freight access between the
12 Interbay/Ballard areas and the SODO and Duwamish industrial areas. It is an
13 important alternative route to I-5, the most heavily used highway in the Pacific
14 Northwest. SR 99 also provides an important link to major league sports
15 stadiums at the south end of downtown and access to I-90 for trips coming from
16 northwest Seattle.

17 Within the study area, SR 99 is classified as an “Other Urban Expressway” and
18 has been designated as part of the Washington State National Highway System.
19 The roadway was designed in the 1940s and was open for traffic in 1953. SR 99 is
20 an at-grade facility as it enters downtown Seattle from both the north and south.
21 However, between S. Holgate Street and the Battery Street Tunnel, SR 99 is a
22 double-level viaduct facility with two to four lanes available in each direction and
23 no shoulders. One full interchange and four partial interchanges are located
24 within the study area, and there are a number of streets where drivers can access
25 SR 99 via right-on and right-off maneuvers in the South Lake Union area.

26 4.1.2 Other Freeways, Highways, and Expressways

27 I-5 is a major Urban Interstate freeway that runs the length of the west coast from
28 the Mexican border south of San Diego, California, to the Canadian border north
29 of Bellingham, Washington. I-5 is the most used and most important highway
30 corridor in the region. Within the study area, I-5 runs north-south just east of
31 downtown. The corridor serves a number of roles, including freight transport,
32 commuting, and longer-distance regional trips.

33 The roadway varies from two to five travel lanes in each direction, with
34 additional collector-distributor lanes providing access to downtown ramps and
35 accommodating merging traffic from I-90. Only two continuous lanes are
36 provided through downtown in each direction, as other lanes are added or
37 dropped to provide access in downtown.

1 In addition to the mainline, a reversible set of express lanes provides HOV access
2 to and from downtown and additional capacity for general-purpose through
3 traffic. This facility operates southbound during the morning commute and
4 northbound at other times.

5 There are five interchanges on I-5 within the study area. The I-5/I-90 interchange
6 is by far the largest and most complicated of the interchanges, providing access to
7 a number of arterials in south downtown, as well as the two interstates. A
8 number of entrance and exit points are located between James and Stewart Streets
9 that directly access downtown Seattle. The interchange at Mercer Street provides
10 the main access point to the northern study area and South Lake Union.

11 4.1.3 Arterial and Local Streets

12 Nearly all of the downtown area streets are designated as either a principal or
13 minor arterial. Principal arterials make up the majority of the central downtown
14 area between Yesler Way and Denny Way. Principal arterials provide major
15 north-south travelways, with a mixture of minor and collector arterials providing
16 travel opportunities in the east and west directions.

17 While SR 99 is designated as an “Other Urban Expressway” and the majority of
18 trips travel through the downtown area, approximately 62 percent of all users
19 (vehicle and transit) on the viaduct on a daily basis have one trip-end in
20 downtown Seattle. Therefore, connections to the downtown street network are of
21 considerable importance.

22 Recent Improvements to Local Streets

23 Since the 2006 Supplemental Draft EIS was published, recent improvements have
24 been made to Westlake Avenue. Westlake Avenue and Westlake Avenue N.
25 between Blanchard Street and Valley Street was restriped from one-way traffic to
26 two-way traffic in the fall of 2007 to prepare for the South Lake Union Streetcar.
27 Westlake Avenue N. was restriped for two northbound and two southbound
28 travel lanes. New left-turn pockets were added at Valley Street, Mercer Street,
29 Republican Street, and Denny Way, with on-street parking on both sides of
30 Westlake Avenue between Republican Street and Denny Way.

31 4.1.4 Travel Demand and Traffic Patterns

32 Vehicle Miles of Travel

33 VMT provide a measure of vehicle demand on the four-county regional roadway
34 network. In short, VMT is the product of the number of vehicles traveling over
35 the sum total of roadways in the transportation network times the length of
36 roadways in that network. The existing conditions (2005) total for daily VMT is

1 estimated to be approximately 73,623,000. During the AM peak period, regional
 2 VMT is estimated at about 13,800,000 and PM peak period VMT is estimated to be
 3 16,116,000. VMT is shown in Exhibit 4-2.

4 **Vehicle Hours of Travel**

5 VHT provide an estimate of how long travelers spend on the roadway system.
 6 Daily VHT for existing conditions is estimated to be 2,022,000. During the AM
 7 peak period, the VHT is estimated to be 452,000, while the PM peak period, the
 8 estimate is 518,000. VHT is shown in Exhibit 4-2.

9 **Vehicle Hours of Delay**

10 VHD measure the number of hours of travel on a transportation network that are
 11 considered to be operating at less than optimum speeds. VHD is often considered
 12 as an indicator of congestion levels. Daily VHD for existing conditions is
 13 estimated to be 385,000. VHD for the AM peak period is 138,000, while the PM
 14 peak period is estimated to be 150,000. VHD is shown in Exhibit 4-2.

15 **Exhibit 4-2. VMT, VHT, and VHD for Center City and Region**

Performance Measure	AM Peak	PM Peak	Daily
Seattle Center City			
VMT	385,400	472,400	2,118,200
VHT	13,200	17,600	67,500
VHD	3,500	5,400	14,500
Four-County Region			
VMT	13,830,000	16,116,800	73,622,500
VHT	452,100	517,800	2,021,800
VHD	137,600	149,900	384,800

16 Notes:

17 ¹ VMT = Vehicle Miles of Travel

18 ² VHT = Vehicle Hours of Travel

19 ³ VHD = Vehicle Hours of Delay

20 ⁴ The VMT, VHT, and VHD estimates do not include centroid connectors in the calculations.

21 **Alaskan Way Viaduct (SR 99) Users**

22 SR 99 travels north-south, passing through downtown Seattle on the Alaskan
 23 Way Viaduct. I-5 parallels SR 99 through downtown, and together they are the
 24 primary north-south corridors in Seattle. SR 99 connects west-side communities
 25 such as West Seattle, Burien, Ballard, and Greenwood with each other and
 26 downtown. The following sections present data that describes users of SR 99
 27 within the study area for existing conditions (2005 analysis year).

1 Existing SR 99 Daily Traffic Patterns

2 Exhibit 4-3 shows the existing daily traffic patterns on SR 99 within the study
3 area. Blue lines indicate trips that use the viaduct (SR 99 between the stadium
4 area and Battery Street Tunnel), while red lines show trips that use SR 99 (Aurora
5 Avenue), but enter or exit north of the viaduct. Arrows indicate locations where
6 traffic enters or exits the corridor, with each arrow representing a ramp
7 movement. Because access in the South Lake Union area is provided by many
8 closely spaced cross-streets, these movements are shown grouped.

9 At the north end of the study area (on Aurora Avenue), almost half of trips using
10 SR 99 enter and exit the corridor north of the Battery Street Tunnel. Of the 84,800
11 daily vehicle trips on Aurora Avenue, 36,400 trips enter and exit in the South
12 Lake Union area.

13 Some 63,500 vehicles use the Battery Street Tunnel on a typical weekday. They
14 include the remainder of the Aurora Avenue trips, as well as 15,100 additional
15 trips entering and exiting the corridor in the South Lake Union area. A relatively
16 small number of trips enter or exit at the Battery Street ramps in the Belltown
17 area. About 6,600 vehicles exit southbound and enter northbound at this location
18 at the south portal of the Battery Street Tunnel.

19 The Elliott and Western ramps are major access points to the corridor. About
20 34,500 vehicles enter SR 99 southbound on the Elliott Avenue on-ramp and exit
21 on the Western Avenue off-ramp. These connections provide access to Belltown,
22 Uptown, and points farther north, including the Ballard/Interbay areas via 15th
23 Avenue W.

24 In downtown, 19,800 vehicles join southbound SR 99 from the Columbia Street
25 on-ramp and exit northbound via the Seneca Street off-ramp. South of these
26 ramps, the viaduct carries its highest level of traffic: 111,200 vehicles on a typical
27 weekday.

28 South of midtown, a total of 24,200 vehicles exit southbound in the stadium area
29 on the First Avenue S. off-ramp and enter northbound on the corresponding on-
30 ramp. This is the last connection in the greater downtown area, as no other
31 connections are provided until S. Spokane Street. At S. Spokane Street,
32 33,100 vehicles exit the corridor southbound to either the West Seattle high bridge
33 or the low bridge to Harbor Island and enter SR 99 northbound from the West
34 Seattle high bridge. Approximately 53,900 trips continue southbound and enter
35 northbound to and from E. Marginal Way.

36 Southbound, 12,000 vehicles exit in the stadium area on the First Avenue S. off-
37 ramp and 11,300 vehicles enter northbound on the corresponding on-ramp. This
38 is the last connection in the greater downtown area, as no other connections are

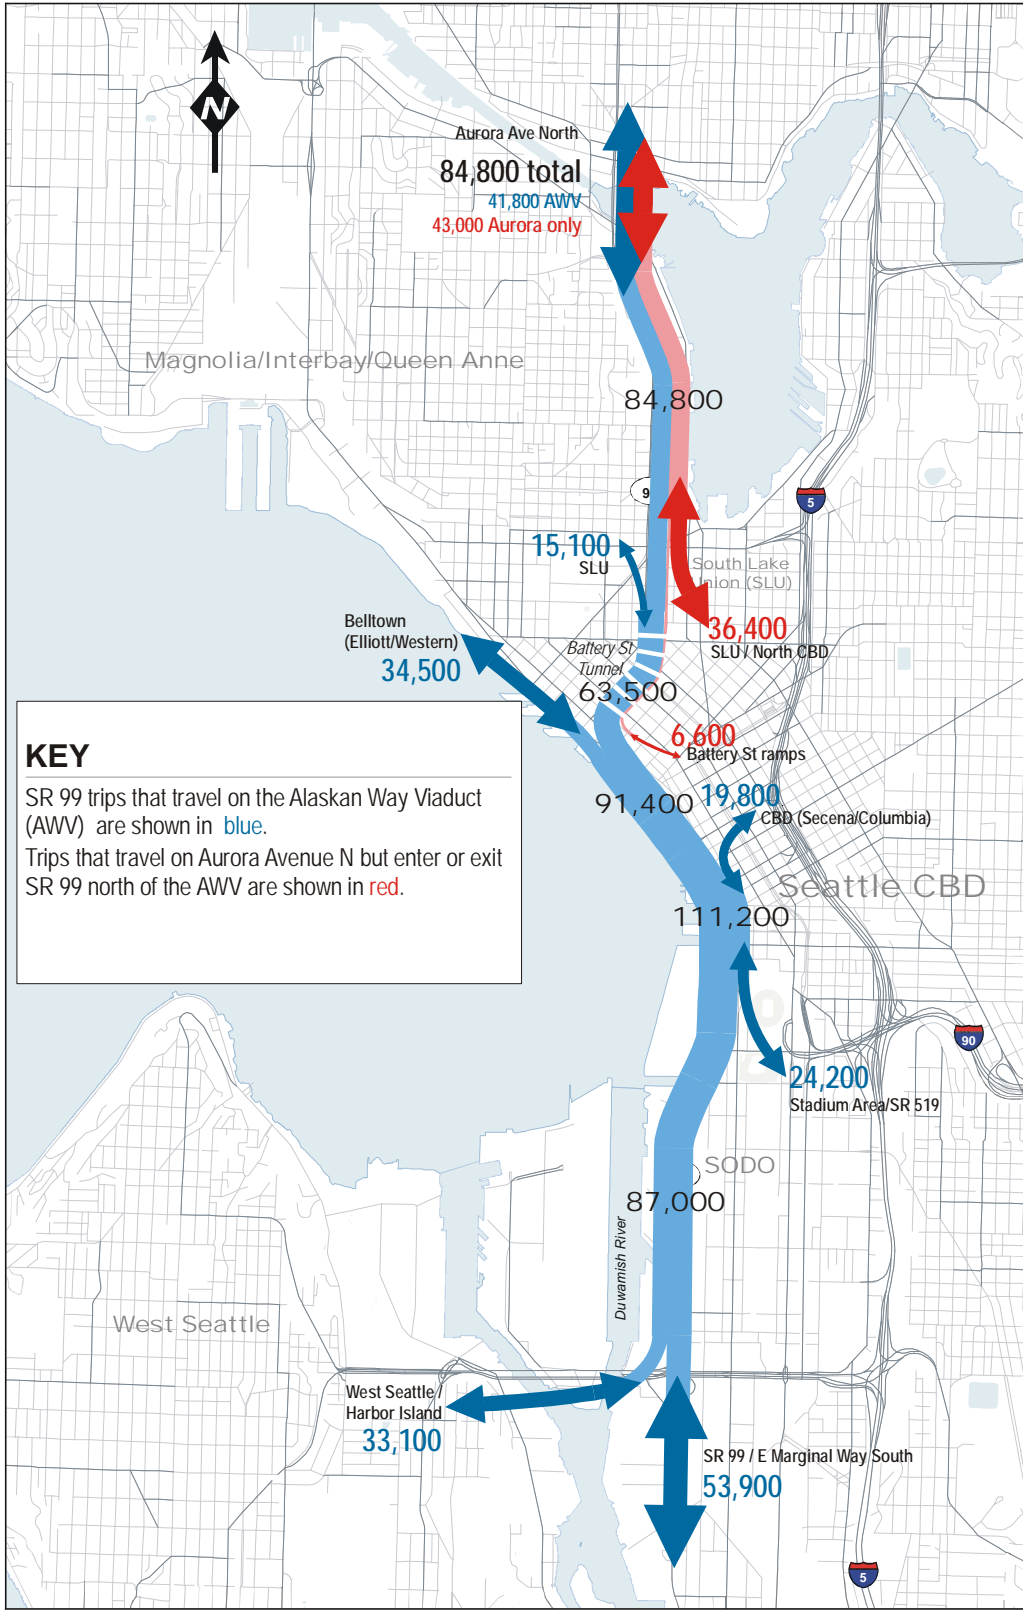

Exhibit 4-3
Existing (2005) Daily SR 99 Traffic Patterns

1 provided until S. Spokane Street. At S. Spokane Street, 16,200 vehicles exit the
 2 corridor to either the West Seattle high bridge or the low bridge to Harbor Island.
 3 Northbound, 16,900 vehicles enter SR 99 from the West Seattle high bridge.
 4 Approximately 25,900 trips continue south to E. Marginal Way. The
 5 corresponding northbound volume entering from E. Marginal Way is
 6 27,900 vehicles.

7 Origins and Destinations of AWW Trips

8 The origins and destinations of trips using the viaduct were estimated from travel
 9 demand model assignments. During the morning commute, the highest
 10 concentration of AWW trip origins are in the downtown, Queen Anne, Fremont,
 11 Ballard, and West Seattle neighborhoods. Trips beginning as far north as
 12 Snohomish County and as far south as Pierce County also use SR 99. These trips
 13 primarily originate from westside communities (e.g., Burien, Shoreline, White
 14 Center). Destinations are more concentrated, with most trips accessing work and
 15 commercial sites downtown, in the Ballard/Fremont/Interbay areas northwest of
 16 downtown, and to the south, in the SODO and Duwamish industrial areas. West
 17 Seattle, the University of Washington, and Sea-Tac Airport are other primary
 18 destinations during the AM peak.

19 Existing daily trips along the viaduct were also estimated using travel demand
 20 model assignments. The majority of trips using the viaduct are going to or
 21 coming from the CBD of downtown Seattle. Approximately 20 percent of all
 22 users travel along the viaduct through the core downtown, but are destined to
 23 nearby locations just north or south of downtown, such as South Lake Union,
 24 Queen Anne, Capitol Hill, or SODO. The remaining trips that use the viaduct are
 25 longer-distance trips, such as trips from Ballard to Burien. Exhibit 4-4 lists
 26 the percentage of daily trips to downtown and other areas.

27 **Exhibit 4-4. Model Estimated Origins/Destinations of Existing Daily Person Trips**
 28 **Using the Alaskan Way Viaduct**

	Downtown Seattle	Areas Near Downtown ¹	Longer-Distance Trips
Auto	58%	24%	18%
Auto + Transit	62%	21%	17%

29 ¹ South Lake Union, Queen Anne, Capitol Hill, South Downtown.

30 Modeled Traffic Volumes

31 Exhibit 4-5 depicts the modeled distribution of daily traffic on north-south
 32 oriented highways and streets entering the study area from the north and south,
 33 as well as in the central downtown Seattle area. I-5 carries the majority of traffic
 34 through the study area, approximately 53 percent in the downtown area. SR 99

1 carries about 23 percent of traffic in the central downtown area, while the local
 2 streets in downtown combined carry approximately 24 percent of daily north-
 3 south traffic.

4 **Exhibit 4-5. Existing (2005) Model-Estimated Daily Traffic Distributions**

	Existing Daily Traffic (vehicles)
Alaskan Way	
North (North of Thomas Street)	N/A
Central (North of Columbia Street)	12,000
South (South of S. King Street)	12,000
North-South Arterials West of I-5 (Except SR 99)	
North (North of Thomas Street)	154,000
Central (North of Seneca Street)	97,000
South (South of S. King Street)	70,000
SR 99 (AWV)	
North (North of Thomas Street)	88,000
Central (North of Seneca Street)	91,000
South (South of S. King Street)	87,000
I-5 (Main and Reversible/HOV)	
North (North of Thomas Street)	292,000
Central (North of Seneca Street)	243,000
South (South of S. King Street)	256,000
TOTAL VEHICLE TRAFFIC	
North (North of Thomas Street)	534,000
Central (North of Seneca Street)	443,000
South (South of S. King Street)	425,000

5
 6 North of downtown, SR 99's share of traffic decreases relative to local streets or
 7 I-5. South of downtown, SR 99 carries about 24 percent of traffic. SR 99 carries
 8 more traffic than any single facility in the study area other than I-5.

9 Modeled Transit Ridership

10 SR 99 is an important transit corridor that provides access into the downtown
 11 area from neighborhoods and communities to the north and south. SR 99 carries
 12 a model-estimated 11,900 transit riders per day north of downtown, and 14,300
 13 riders per day south of downtown (Exhibit 4-6). About 25 percent of transit riders
 14 entering or leaving downtown from the south currently use bus routes that travel
 15 on SR 99. Most of the riders are from the West Seattle area.

1 Exhibit 4-6. Existing (2005) Model-Estimated Daily Transit Ridership

	Existing Transit Ridership (persons)
Buses on SR 99	
North (North of Thomas Street)	11,900
Central (North of Seneca Street)	N/A
South (South of S. King Street)	14,300
Other north-south transit (bus or rail) routes in Seattle	
North (North of Thomas Street)	78,100
Central (North of Seneca Street)	90,200
South (South of S. King Street)	42,200
TOTAL Daily Transit Passengers	
North (North of Thomas Street)	90,000
Central (North of Seneca Street)	90,200
South (South of S. King Street)	56,500

2 Modeled Person-Trips

3 Analysts use person-trips to measure the number of people, rather than vehicles,
 4 which travel on the transportation system. Increased use of transit or carpools
 5 can increase the overall number of people conveyed, even if vehicle traffic does
 6 not increase.

7 Exhibit 4-7 summarizes model-estimated daily person-trips at screenline
 8 locations. The figures reported include all trip purposes (e.g., work trips,
 9 commercial trips, non-work trips).

10 Exhibit 4-7. Existing (2005) Model-Estimated Daily Person Throughput at Selected
 11 Screenlines

Screenline Location	Total Person Throughput	Transit Riders
North (North of Thomas Street)	672,900	90,000
Central (North of Seneca Street)	585,100	90,200
South (South of S. King Street)	644,700	56,500

12

13 4.1.5 Roadway Connectivity and Access

14 SR 99 is a regional facility, but it primarily serves shorter regional trips and
 15 intracity trips. Between S. Spokane Street and the Battery Street Tunnel, all access
 16 is provided via ramps. North of the Battery Street Tunnel, arterial connections to
 17 the SR 99 mainline provide access (right turn on/right turn off only). This section
 18 describes the SR 99 corridor through the study area.

1 **Travel Lanes**

2 The SR 99 facility comprises two or more general-purpose lanes in each direction
3 through the study area. Exhibit 4-8 depicts the number of lanes on SR 99
4 throughout the corridor. Northbound, the SR 99 corridor carries three lanes from
5 S. Spokane Street to the First Avenue S. ramps, four lanes to the Seneca Street off-
6 ramp, and three lanes to the Western Avenue off-ramp. Two lanes continue
7 northbound into the Battery Street Tunnel. Southbound, two lanes exiting the
8 Battery Street Tunnel are joined by a third lane entering from Elliott Avenue. The
9 three-lane southbound segment is carried through the corridor, merging to a two-
10 lane segment south of S. Spokane Street. The Battery Street Tunnel operates with
11 two lanes in each direction. Exiting the tunnel northbound, the highway is joined
12 by two additional lanes from Denny Way. The four-lane segment continues
13 intermittently to Aloha Street, where the outside lane is dropped to an off-ramp.
14 The three-lane segment continues beyond the study area. In the southbound
15 direction, three lanes are provided north of the Denny Way off-ramp at the
16 Battery Street Tunnel. In this area north of the Battery Street Tunnel, the outside
17 lane serves to collect and distribute right-turning vehicles to side streets.
18 Through movements are primarily accommodated in the inside lanes.

19 **Access to SR 99**

20 Exhibit 4 9 summarizes connections currently provided between SR 99 and other
21 facilities. To summarize the quality of access the connections provide, a
22 qualitative rating system grades the degree (full access, partial access, or no
23 access) and quality of connections (ranging from direct ramp connections to
24 indirect connections). Transit connections are addressed separately as part of the
25 Transit section (Section 4.4).

26 To/From West Seattle

27 Access and egress to SR 99 is provided at several locations. At S. Spokane Street,
28 an eastbound to northbound on-ramp provides access from West Seattle, while in
29 the opposing direction a southbound to westbound off-ramp provides for the
30 reciprocal movement to the West Seattle high bridge. The southbound off-ramp
31 also provides access to Harbor Island and the West Seattle low bridge.

32 To/From Stadium Area

33 Near the stadium area, ramps at First Avenue S. provide access to northbound
34 SR 99 and egress from southbound SR 99. New connections to the south will be
35 provided as part of the S. Holgate Street to S. King Street Viaduct Replacement
36 Project.

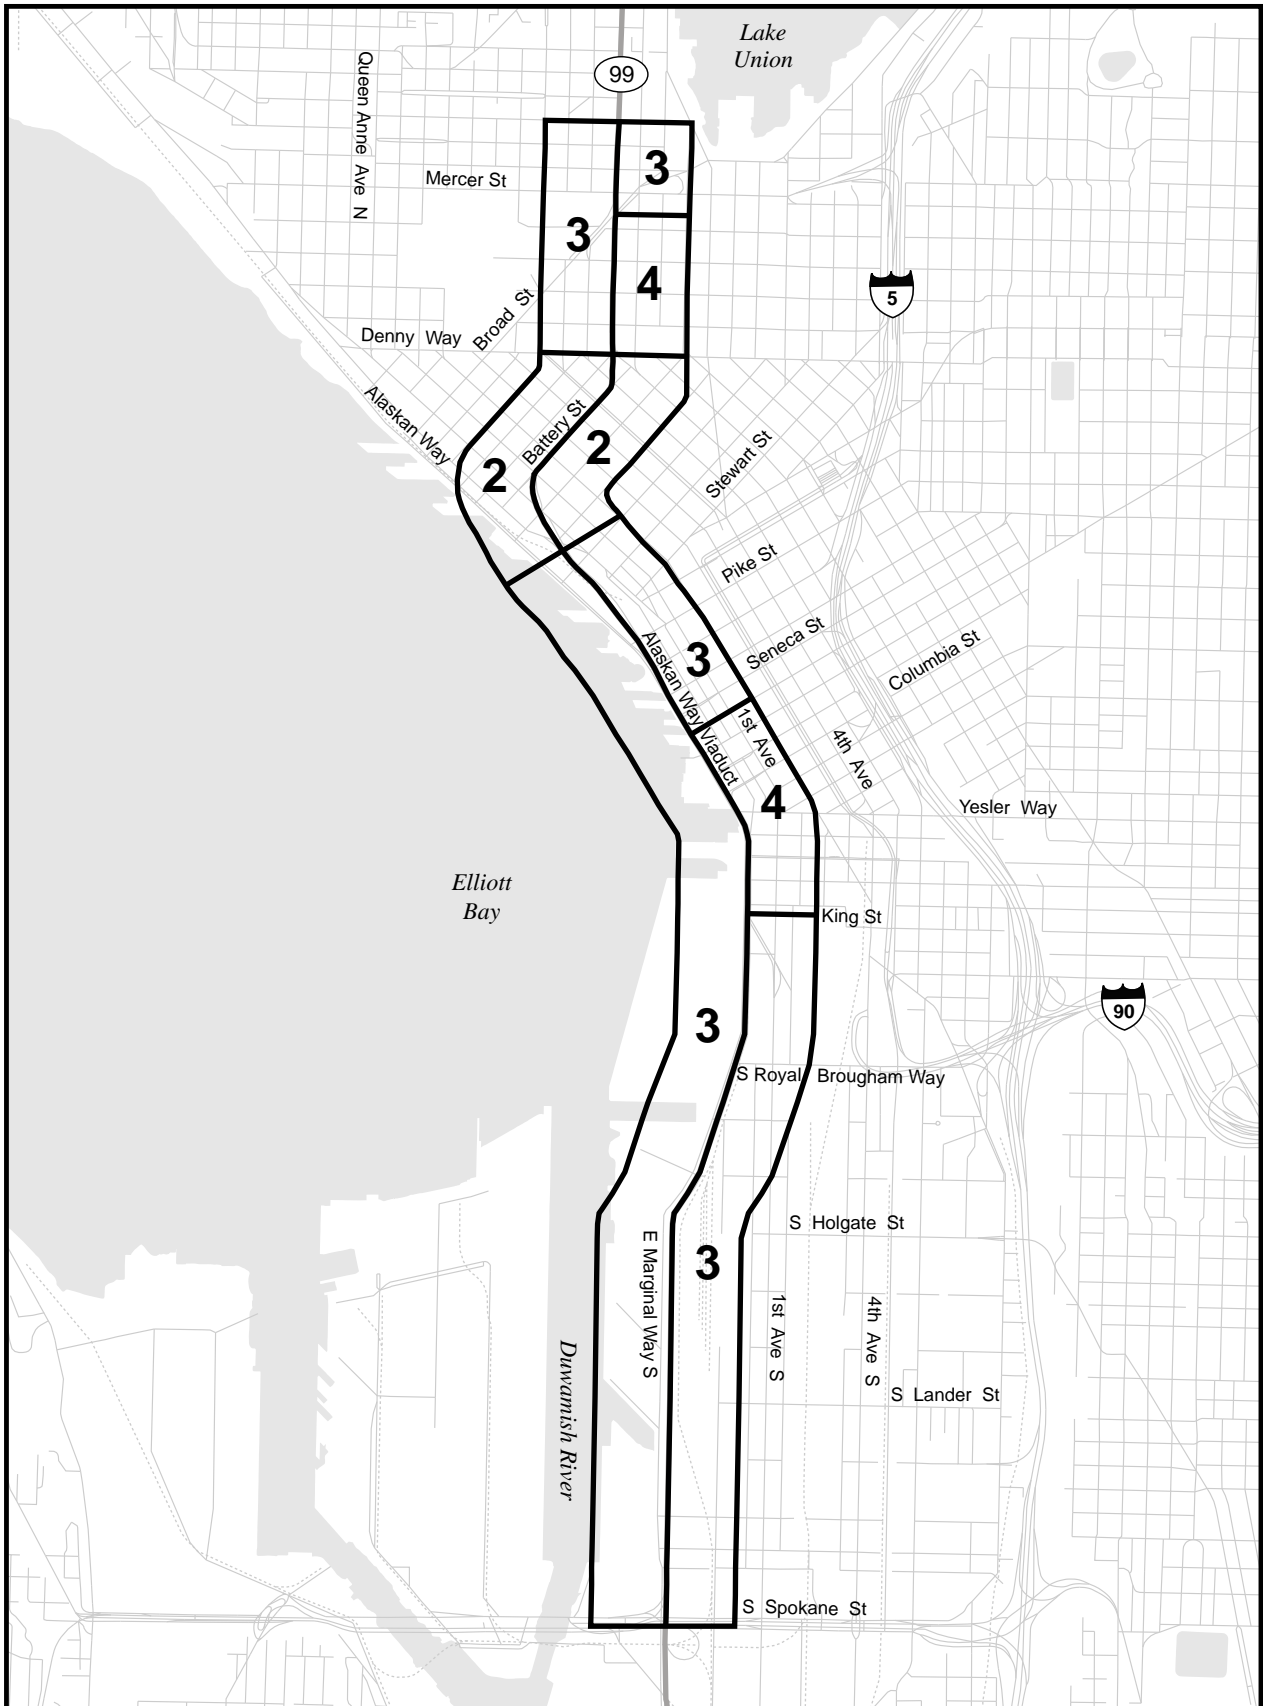

Exhibit 4-8
SR 99 Lane Configuration

1 Exhibit 4-9. Existing Connections

- 1 SB = southbound, NB = northbound, EB = eastbound, WB = westbound
- 2 ¹ For example, access to SB SR 99 from EB Roy, Harrison, or Thomas Streets after crossing to the west side of
- 3 SR 99 by Broad Street or Denny Way.
- 4 ² For example, access from NB SR 99 from EB Roy, Republican, Harrison, or Thomas Streets, to Dexter
- 5 Avenue, to WB Broad Street or Denny Way.

6 To/From Downtown

7 In downtown Seattle, a northbound off-ramp connects to Seneca Street, while an
 8 on-ramp from Columbia Street provides access from downtown to southbound
 9 SR 99. These midtown ramps provide access to the CBD, including the retail and
 10 financial districts, and are also the downtown transit access point for routes
 11 traveling to and from the south. No direct access to and from the north is
 12 provided in the downtown area.

13 To/From Elliott and Western Avenues

14 In the Belltown area, an interchange at Western Avenue and Elliott Avenue
 15 provides access to north downtown, Pike Place Market, and the waterfront, as
 16 well as access to arterials connecting to Interbay, Uptown, Magnolia, and Ballard.
 17 The roadway and ramp geometrics for the southbound off-ramp and northbound
 18 on-ramp, which are near the Battery Street Tunnel portal, limit overall use of
 19 these ramps.

1 To/From South Lake Union Area

2 The Denny Way ramps provide access to north downtown and a variety of
3 locations to the east and west of SR 99 (South Lake Union, Seattle Center, Queen
4 Anne, the north waterfront and Port of Seattle facilities), and are also the transit
5 access point for all routes traveling on the corridor between downtown and
6 points north.

7 In the South Lake Union area, an off-ramp to Mercer Street provides direct access
8 to the South Lake Union neighborhood for northbound traffic, while the Broad
9 Street exit provides access to Seattle Center and Queen Anne for southbound
10 traffic. Other access in the South Lake Union area is provided by a number of
11 right-on and right-off access points connecting to the local street grid. No left
12 turns or at-grade crossings of SR 99 are allowed. Access at these locations is
13 somewhat limited because the side streets enter at right angles, requiring that
14 drivers accelerate from a stopped position when entering or decelerate
15 considerably before exiting SR 99.

16 **Design Constraints**

17 The design of SR 99 in the study area is substandard in several locations.
18 Throughout the study area, the mainline provides narrow travel lanes and limited
19 shoulders. Battery Street Tunnel users experience low speeds due to an existing
20 curve designed for between 35 and 40 miles per hour (mph) and narrow
21 shoulders. In the southbound direction, the off-ramp at Western Avenue
22 provides no deceleration length and limited sight lines for vehicles using the
23 ramp due to the sudden vertical drop upon exiting the mainline. The left-side on-
24 ramp at Columbia Street requires low speeds followed by a short acceleration
25 length. Finally, the left-side off-ramp at First Avenue S. provides a short
26 deceleration lane.

27 In the northbound direction, the off-ramp at Seneca Street requires low speeds
28 due to a very tight curve upon leaving the mainline. Congestion forming at the
29 Seneca ramp exit slows traffic on the viaduct. Also northbound, the on-ramp to
30 SR 99 at Battery Street merges immediately with the mainline without an
31 acceleration length and has limited sight distance.

32 Transport of combustible materials through the Battery Street Tunnel is
33 prohibited at all times and is also prohibited from the viaduct during peak
34 commuting hours.

35 **Speed Limits**

36 Posted speed limits on the SR 99 mainline are shown in Exhibit 4 10.

1 **Exhibit 4-10. Posted Speed Limits on SR 99 (miles per hour)**

Mainline Segment	Posted Speed Limit (NB and SB)
North of Denny Way	40
Battery Street Tunnel	40 (35 advisory)
Elliott/Western Ramps to Seneca/Columbia Ramps	50
Seneca/Columbia Ramps to First Avenue S. Ramps	50
First Avenue S. Ramps to S. Spokane Street	50 (40 trucks)
South of S. Spokane Street	50

2 NB = northbound; SB = southbound

3 **4.2 Traffic Operations on SR 99**

4 **4.2.1 Alaskan Way Viaduct Mainline and Ramp Volumes**

5 This section describes the AM peak hour, PM peak hour, and daily traffic volume
6 estimates for the existing (2005) SR 99 mainline and ramps.

7 **AM Peak Hour**

8 Traffic volumes on the SR 99 corridor are highest during commuting hours. In
9 the morning, peak hour traffic volumes on SR 99 are fairly directional, with
10 heavier volumes entering the central downtown. At the north end of the study
11 area, AM peak hour mainline volumes are higher in the southbound direction, as
12 more vehicles are entering the downtown area (4,160 vehicles) than are leaving it
13 (2,630 vehicles). Southbound off-ramp volumes at Denny Way (1,230 vehicles)
14 exceed those on the northbound on-ramp (430 vehicles). In the Battery Street
15 Tunnel, the volumes are fairly balanced, with the volume of northbound vehicles
16 (2,850 vehicles) slightly exceeding the volume of southbound vehicles
17 (2,640 vehicles). The Battery Street Tunnel ramps providing access to and from
18 the north show directionality, with 410 vehicles exiting southbound and only
19 150 vehicles entering northbound. The ramps to and from the south at Elliott and
20 Western Avenues show directionality as well, with 1,130 vehicles entering
21 southbound and 1,330 vehicles exiting northbound.

22 The downtown ramps providing access to and from the south show the opposite
23 directionality as those to the north, with more vehicles exiting northbound at
24 Seneca Street (1,050 vehicles) than entering southbound at Columbia Street
25 (350 vehicles). The First Avenue S. ramps show similar directionality favoring
26 travel to central downtown, with 1,410 vehicles exiting southbound but only
27 760 vehicles entering northbound. South of downtown and in the stadium area,
28 mainline volumes are considerably higher in the northbound direction
29 (4,320 vehicles) than the southbound direction (2,300 vehicles). At S. Spokane

1 Street, volumes entering northbound from West Seattle (1,630 vehicles) are over
2 double those exiting southbound to West Seattle (660 vehicles). AM peak hour
3 mainline and ramp volumes are shown in Exhibit 4 11.

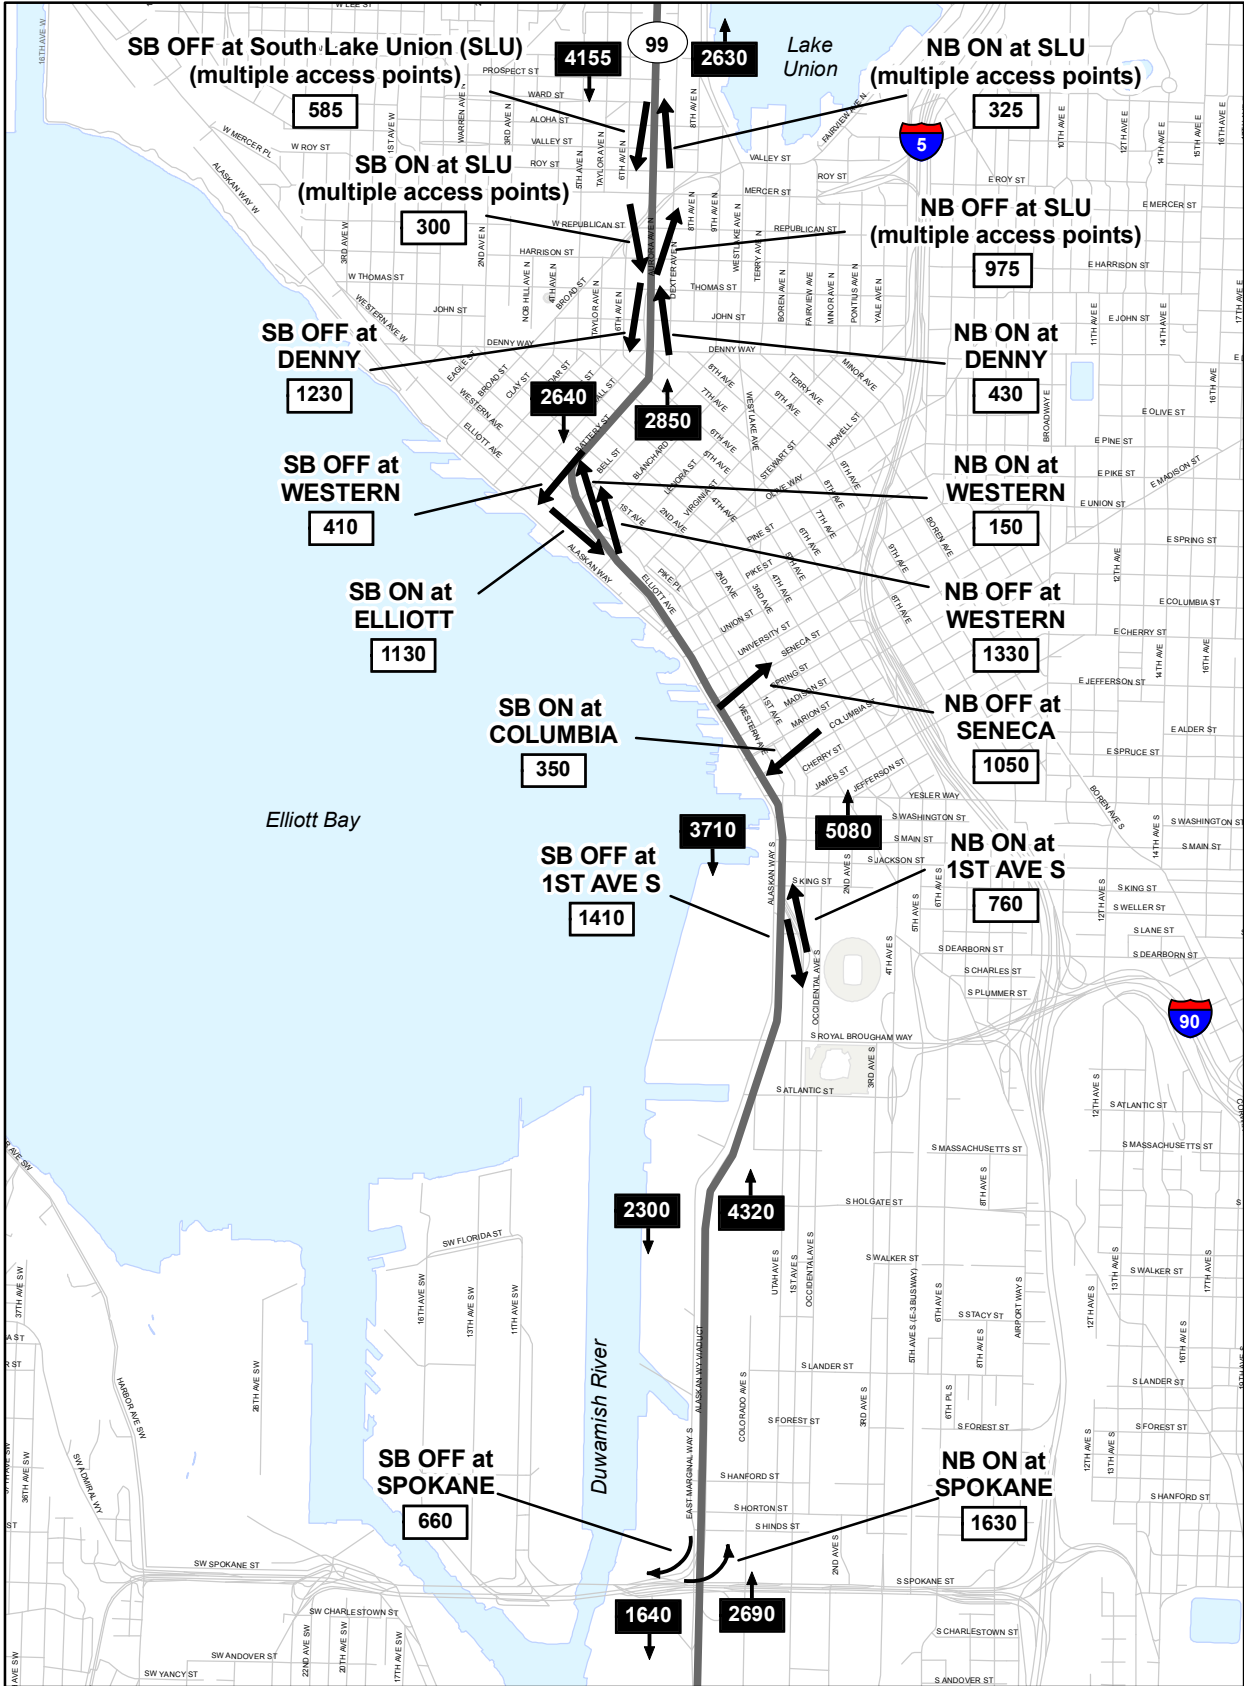

4 **PM Peak Hour**

5 Similar to the AM peak, the PM peak hour traffic volumes along SR 99 are
6 directional, with heavier volumes leaving the central downtown. At the north end
7 of the study area, PM peak hour mainline volumes are higher in the northbound
8 direction, as more vehicles are leaving the downtown area (4,300 vehicles) than are
9 entering it (3,345 vehicles). Northbound on-ramp volumes at Denny Way
10 (1,340 vehicles) exceed those on the southbound off-ramp (680 vehicles). In the
11 Battery Street Tunnel, the volume of northbound vehicles (3,260 vehicles) again
12 exceeds the volume of southbound vehicles (2,790 vehicles). The Battery Street
13 Tunnel ramps providing access to and from the north also show directionality,
14 with 490 vehicles entering northbound but only 200 vehicles exiting southbound.
15 The ramps at Elliott/Western to and from the south show directionality as well,
16 with 1,320 vehicles entering southbound and 1,200 vehicles exiting northbound.

17 The downtown ramps providing access to and from the south show the opposite
18 directionality as those to the north, with more vehicles entering southbound at
19 Columbia Street (1,230 vehicles) than those exiting northbound at Seneca Street
20 (680 vehicles). The First Avenue S. ramps show similar directionality, with
21 1,200 vehicles entering northbound but only 810 vehicles exiting southbound.
22 South of downtown and in the stadium area, mainline volumes are considerably
23 higher in the southbound direction (4,330 vehicles) than the northbound direction
24 (3,450 vehicles). At S. Spokane Street, volumes exiting southbound to West Seattle
25 (1,890 vehicles) are almost double those entering northbound from West Seattle
26 (1,110 vehicles). PM peak hour mainline and ramp volumes are shown in
27 Exhibit 4-12.

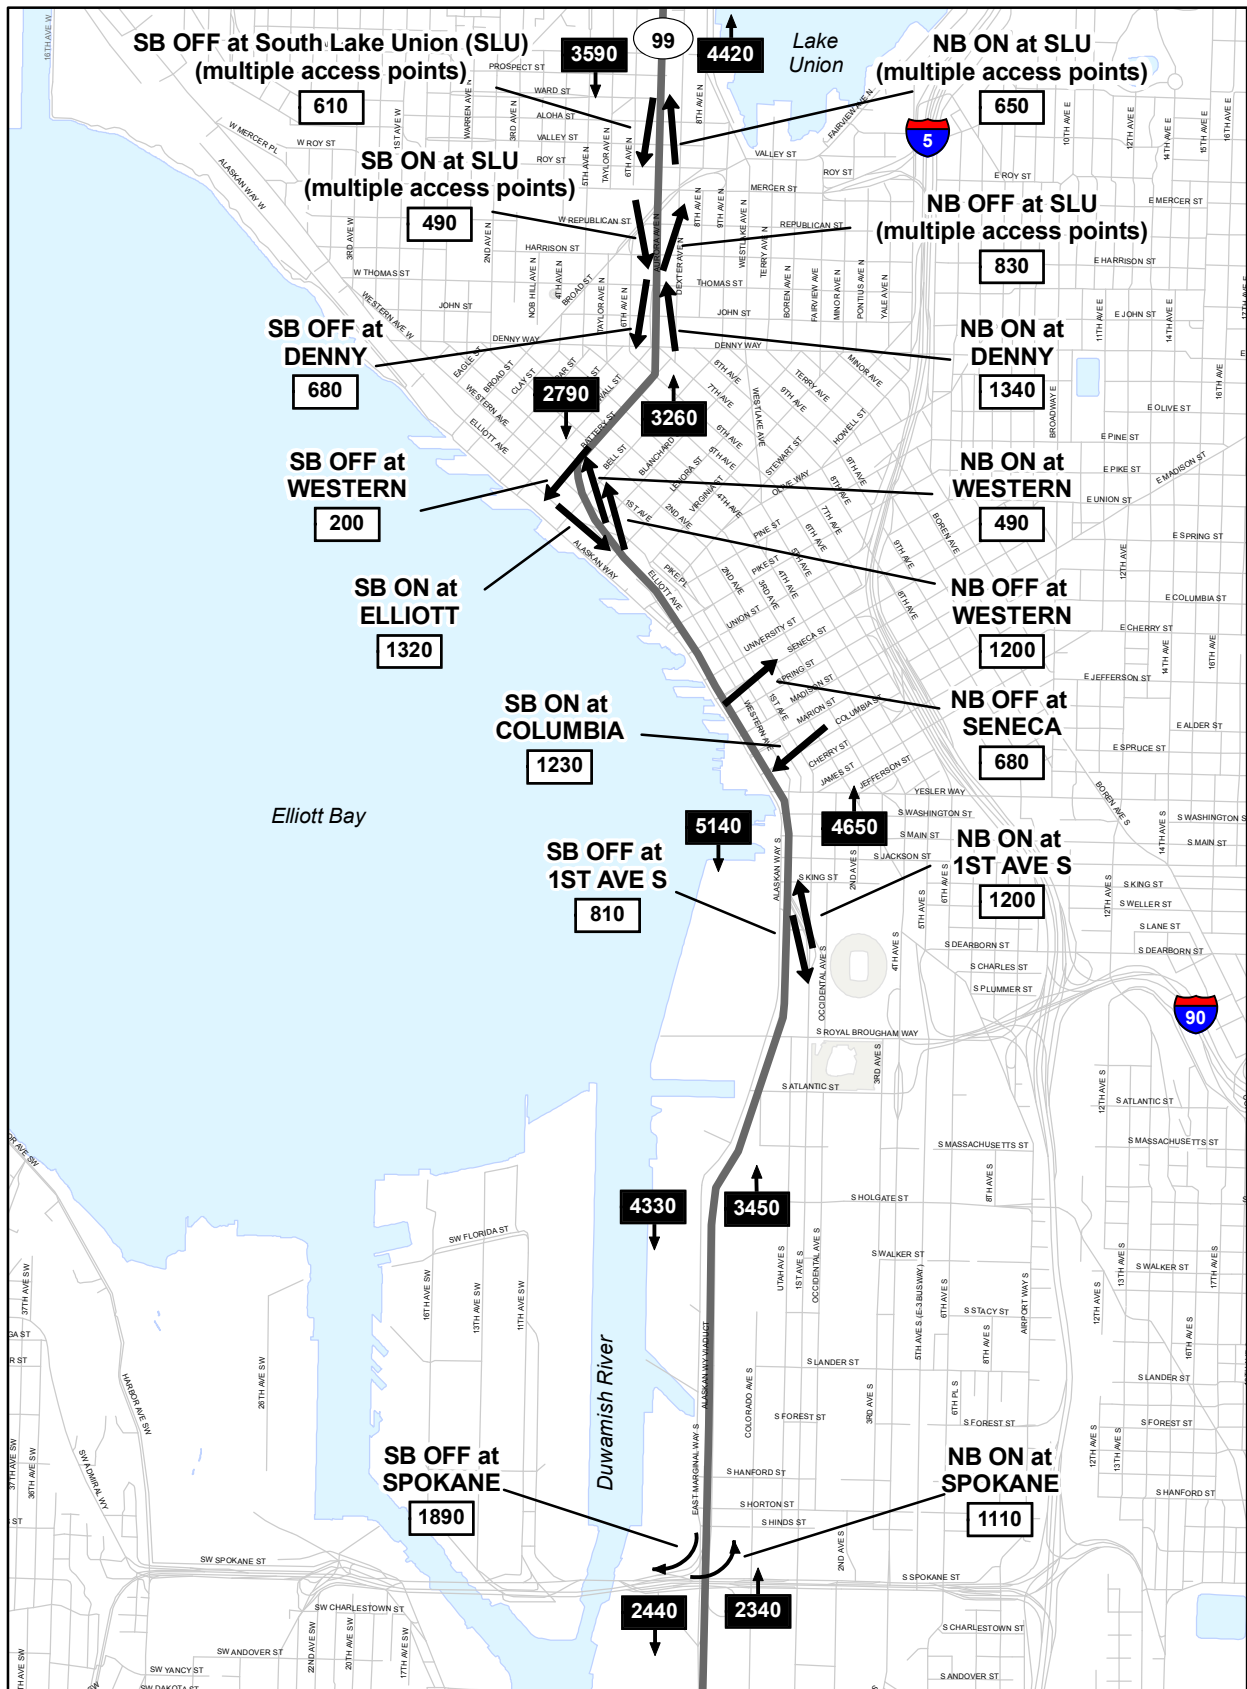

28 **Daily**

29 As expected, daily traffic volumes along SR 99 are generally balanced by
30 direction, with similar volumes leaving the central downtown as entering. At the
31 north end of the study area, the majority of exiting southbound vehicles exit at
32 Denny Way (11,240), with a little more than half that many exiting at the multiple
33 access points in South Lake Union (6,200). Similarly, about 11,050 northbound
34 vehicles enter SR 99 at Denny Way, with 7,900 entering at other South Lake Union
35 access points. In the Battery Street Tunnel, the volume of northbound vehicles
36 (32,450 vehicles) is similar to the volume of southbound vehicles (31,010 vehicles).
37 The ramps at the south end of the Battery Street Tunnel providing access to and
38 from the north are not as balanced as other ramps in the study area on a daily
39 basis, with 3,850 vehicles entering northbound but only 2,740 vehicles exiting

Exhibit 4-12
PM Peak Hour Mainline
and Ramp Volumes -
Existing Conditions (2005)

1 southbound. However, the Elliott/Western ramps to and from the south are
2 relatively balanced, with 17,100 vehicles entering southbound and 17,380 vehicles
3 exiting northbound. These ramps have the highest volume of all ramps in the
4 project area.

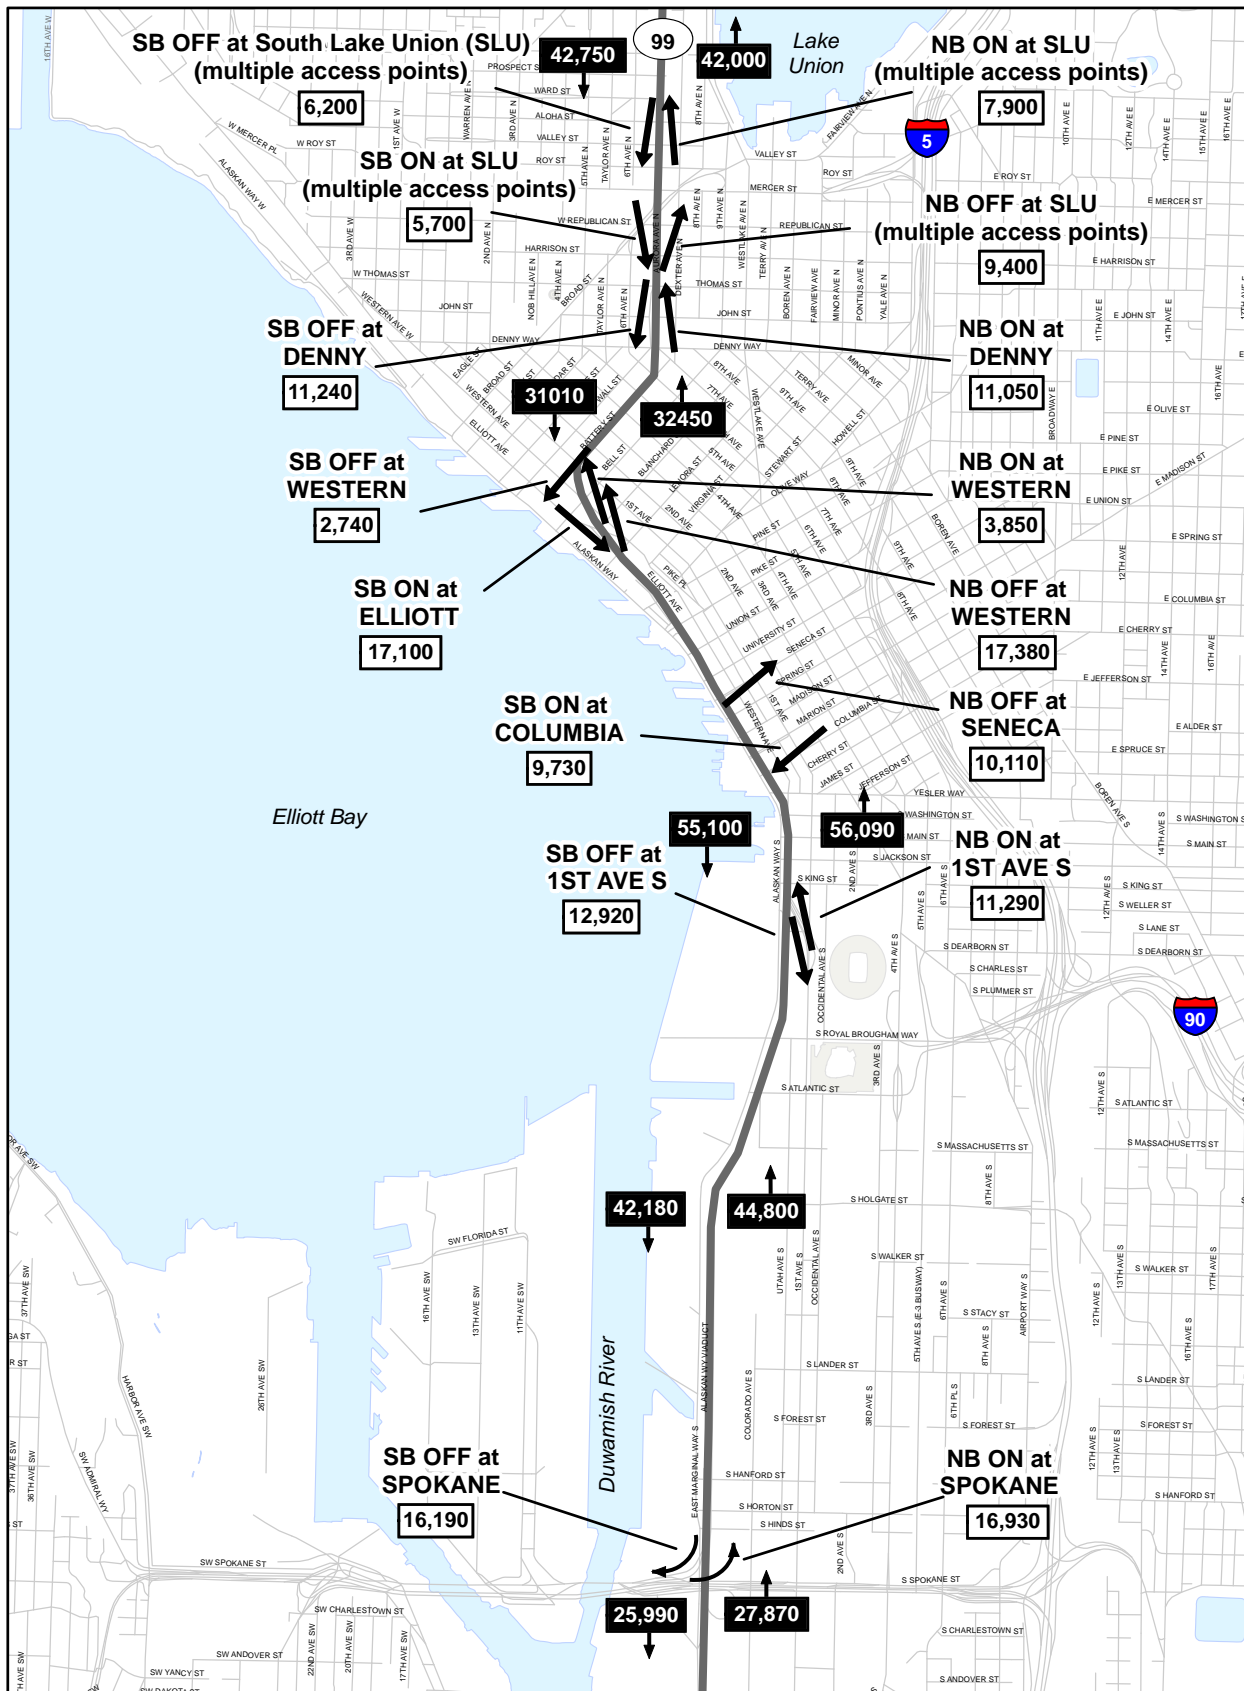

5 The downtown ramps providing access to and from the south are relatively
6 balanced, with 9,730 vehicles entering southbound at Columbia Street and
7 10,110 vehicles exiting northbound at Seneca Street. The First Avenue S. ramps are
8 similarly balanced, with 11,290 vehicles entering northbound and 12,920 vehicles
9 exiting southbound. South of downtown and the stadium area, mainline volumes
10 are somewhat higher in the northbound direction (44,800 vehicles) than the
11 southbound direction (42,180 vehicles). At S. Spokane Street, volumes exiting
12 southbound to West Seattle (16,190 vehicles) are similar to those entering
13 northbound from West Seattle (16,930 vehicles). Daily mainline and ramp volumes
14 are shown in Exhibit 4 13.

15 4.2.2 SR 99 Mainline Level of Service

16 Mainline traffic conditions and ramp interactions for the SR 99 corridor in terms of
17 AM and PM peak hour volumes, travel speeds, and LOS are presented in this section
18 for key mainline segments and related on- and off-ramps.

19 Mainline traffic performance was modeled using VISSIM simulation software.
20 Current AM and PM peak hour LOS estimates for mainline segments were
21 calculated based on simulation results for the SR 99 mainline and are presented in
22 Exhibits 4 14 to 4-17.

23 In the south end of the corridor, mainline traffic operates at LOS B to LOS D in both
24 directions in the AM and PM peak hours. Mainline traffic through midtown
25 generally operates at LOS D to LOS F in both directions in the AM and PM peak
26 hours, with the exception of southbound traffic from the Elliott Avenue on-ramp to
27 the Columbia Street on-ramp during the AM peak hour, which operates at LOS C.
28 Particular areas of congestion include southbound between the Columbia Street left-
29 side on-ramp merge and the left-side off-ramp to First Avenue S. Conditions here
30 are exacerbated by the lack of an acceleration lane for the merge, as well as traffic
31 weaving into the lane to exit at First Avenue S. Northbound traffic also experiences
32 significant congestion due to backups from both the Seneca Street and Western
33 Avenue off-ramps. These backups are due to a combination of substandard
34 geometry on the Seneca Street off-ramp, as well as queues emanating from the ramp
35 termini intersections. Through the Battery Street Tunnel, operations are at or over
36 capacity (i.e., LOS E or F) in both directions in both peak hours. North of the Battery
37 Street Tunnel, operations are at LOS D to LOS E, except for northbound traffic
38 during the AM peak hour, which operates at LOS C.

3 **4.2.3 SR 99 Mainline Speeds**

4 The existing 2005 AM and PM peak hour segment speed results are shown in
 5 Exhibits 4 18 to 4-21 below. These may be compared with the posted speed limits to
 6 gauge the level of delay experienced on the mainline during the AM and PM peak
 7 hours. The posted speed on the northbound mainline is 50 mph between E.
 8 Marginal Way and the Western Avenue off-ramp. North of the Western Avenue
 9 off-ramp, the posted speed drops to 40 mph. The posted speed remains at 40 mph
 10 to the north end of the project limits. The southbound posted speed limit is 40 mph
 11 from the north end of the project area to the Western Avenue off-ramp, where it
 12 increases to 50 mph.

13 Existing estimated speeds on SR 99 in the AM peak hour range from 30 to 49 mph
 14 in the southbound direction and 23 to 47 mph in the northbound direction. In the
 15 PM peak hour, speeds range from 20 to 47 mph in both directions. The segments
 16 with the slowest speeds correspond to the locations with lower LOS, i.e., the Battery
 17 Street Tunnel and midtown sections.

6

1 **4.3 Traffic Operations at Key Arterial Intersections**

2 Traffic operations at signalized intersections in the study area were assessed to
 3 determine intersection LOS and average vehicle delay. The intersection analysis
 4 results are presented for three geographic areas:

- 5 • South
- 6 • Central
- 7 • North

8 Intersections included in the tables below represent those intersections that meet
 9 one or more of the following criteria:

- 10 • Intersection was evaluated in the 2004 Draft EIS or 2006 Supplemental
 11 Draft EIS.
- 12 • Intersection has an LOS of E or worse in either peak period.
- 13 • Intersection is new in 2015 Baseline or 2015 Project.

14 **4.3.1 South**

15 Exhibit 4-22 presents traffic operations for intersections in the south area. There
 16 are no notably congested intersections in the south end, though S. Royal
 17 Brougham Way is estimated to operate at LOS E in the PM peak hour at both First
 18 and Fourth Avenues S. First Avenue S. and S. Atlantic Street also has been
 19 observed to experience relatively long queues, particularly in the PM peak hour.

20 **Exhibit 4-22. Existing (2005) AM and PM Peak Hour Detailed Traffic Operations, South**

2 **4.3.2 Central**

3 Exhibit 4 23 shows AM and PM peak hour signalized intersection LOS and delay
 4 for selected signalized intersections in the waterfront, downtown, and Belltown
 5 areas. First Avenue at Columbia Street operates under congested conditions in
 6 the PM peak hour, with LOS F and an average vehicle delay of 144 seconds. This
 7 intersection serves as the access point to southbound SR 99 from downtown, and
 8 therefore experiences a relatively high volume of traffic.

9 **Exhibit 4-23. Existing (2005) AM and PM Peak Hour Detailed Traffic Operations, Central**

Note: Delay is reported in seconds.

4.3.3 North

In the Uptown and South Lake Union area, one notably congested intersection is at Fairview Avenue N. at Mercer Street, operating at LOS F conditions with an average vehicle delay of over 200 seconds in the PM peak hour, as shown in Exhibit 4-24. This is mainly due to the heavy volume of traffic from the adjacent I-5 ramps. Intersections operating at LOS E include Fairview Avenue N. at Mercer Street and Fairview Avenue N. at the I-5 off-ramp in the AM peak hour. In the PM peak hour, several intersections operate at LOS E, including Western Avenue W. at Elliott Avenue W., Dexter Avenue N. at Mercer Street, and Westlake Avenue N. at Mercer Street.

2 4.4 Transit Services

3 Downtown Seattle is served by a well-developed system of bus transit,
 4 supplemented by a large, regionally implemented vanpool program, Link light
 5 rail between Westlake Center and Tukwila, a waterfront streetcar (currently
 6 suspended), a new South Lake Union streetcar operating between downtown
 7 Seattle and Lake Union, and Sound Transit commuter rail connecting Everett,
 8 Edmonds, Seattle, Tukwila, Kent, Auburn, Sumner, Puyallup, and Tacoma.

9 4.4.1 HOV and Transit Facilities

10 A number of HOV facilities operate in the study area, though none of these relate
 11 directly to the SR 99 corridor. Exhibit 4 25 provides a summary of study area
 12 HOV facilities.

1 **Exhibit 4-25. Existing HOV Facilities and Treatments**

Arterial	From	To	Treatment Description

2 Note: BAT = business access and transit
 3 Source: Seattle Department of Transportation.

4 **Freeway (I-5) HOV Facilities**

5 Within the study area, HOV lanes are provided on I-5 only on the reversible
 6 express lanes. These lanes carry both general-purpose and HOV traffic separately
 7 from the I-5 mainline and operate southbound in the morning and northbound in
 8 the afternoon. In addition to these facilities, HOV lanes are provided on I-5
 9 outside of the study area north of Northgate and south of I-90.

10 **Arterial HOV and Transit-Only Facilities**

11 Several HOV facilities are provided on arterial streets in the study area. Many of
 12 these primarily facilitate transit movement through the downtown area (see

1 Exhibit 4 26). None of the arterial HOV facilities link directly to the SR 99
2 corridor, though the southbound transit lane on Second Avenue and the transit-
3 only left-turn pocket on Alaskan Way are located near the viaduct. Transit
4 routing and use of these facilities is discussed later in this section under Transit
5 Services.

6 In addition to on-street arterial HOV facilities, the transit-only E-3 Busway on
7 Fifth Avenue S., between S. Spokane Street and S. King Street, provides transit
8 access south of downtown between I-5 and the Downtown Seattle Transit Tunnel.

9 **New Arterial HOV and Transit-Only Facilities**

10 Several new arterial HOV and transit-only facilities have been added to the local
11 street system since the 2006 Supplemental Draft EIS was published.

12 Third Avenue

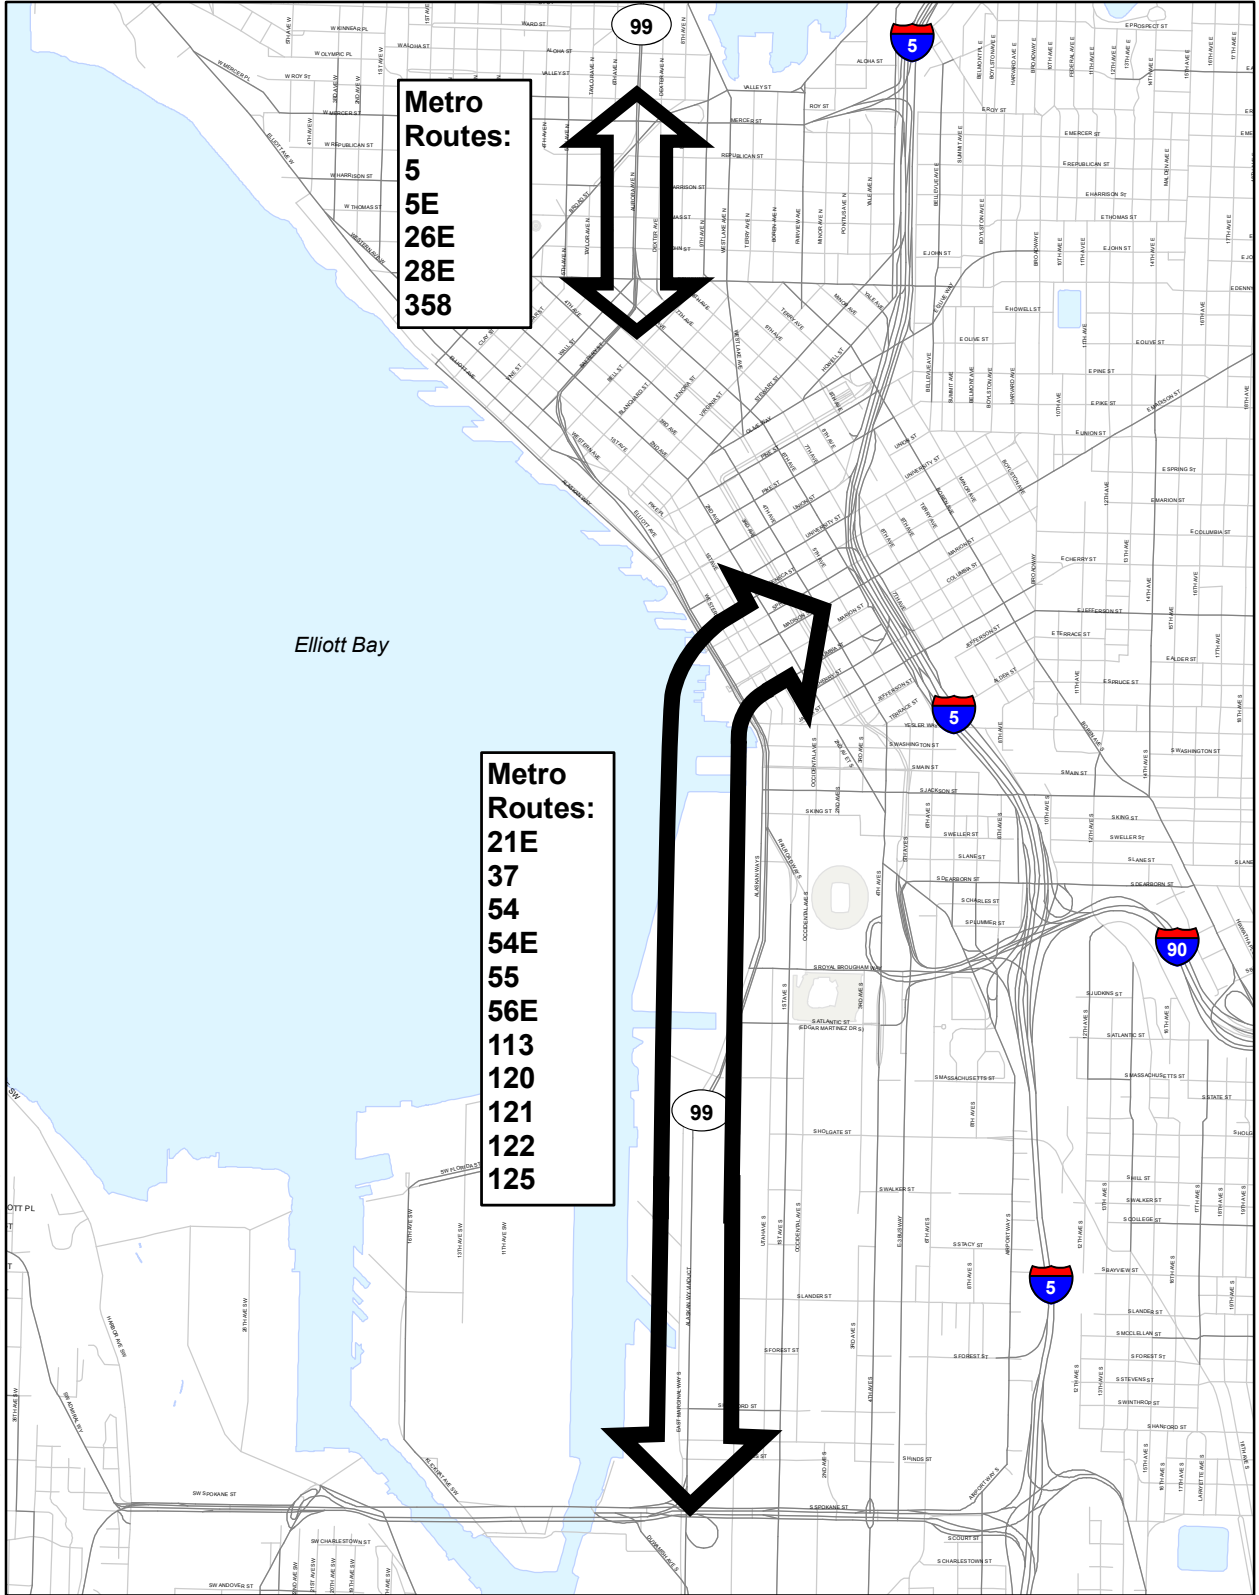

13 Third Avenue, between Stewart Street and Jefferson Street, operates as a transit-
14 only corridor during peak commute hours (6:00 to 9:00 a.m. and 3:00 to 6:30 p.m.).
15 During those periods, other vehicles would have limited circulation and business
16 access. General purpose vehicles have unlimited access to Third Avenue between
17 the hours of 9:00 a.m. and 3:00 p.m., evenings, nights, and on weekends.

18 Business Access and Transit Lanes – 15th Avenue W./Elliott Avenue W.

19 Metro Transit, in coordination with the City of Seattle, is planning a new,
20 streamlined bus service that would make frequent trips all day between Crown
21 Hill and downtown Seattle via Ballard, Interbay, Uptown/Queen Anne, and
22 Belltown. Metro and the City of Seattle are working together on roadway and
23 traffic signal improvements to speed the movement of buses, including business
24 access and transit (BAT) lanes, transit signal priority, and queue jumps.

25 In 2008, curb lanes along 15th Avenue W. and Elliott Avenue W. in both directions
26 between W. Harrison and W. Armour Streets were converted to BAT lanes. In
27 general, BAT lanes are reserved for vehicles intending to turn right at the next
28 signaled intersection (or beforehand, into a business driveway) and for those
29 vehicles merging left after turning into a BAT lane. King County Metro transit
30 vehicles are permitted to pass through signaled intersections without turning
31 right (as are bicycles), but other vehicles may be ticketed for doing so. Parking is
32 allowed in the curb lane for most of the day, but the right-hand turn requirement
33 is in effect at all hours. The BAT lanes are expected to directly benefit the nearly
34 10,000 bus riders that ride through the area each day with minimal disruption to
35 non-bus traffic.

Connections

1 **4.4.2 Transit Services**

2 **Bus Service**

3 As listed in Exhibit 4-27 and Exhibit 4-28, several King County Metro routes use
 4 SR 99/Alaskan Way Viaduct during the peak hours. The ramps that are used are
 5 the northbound off-ramp at Seneca Street, the southbound on-ramp at Columbia
 6 Street, and the ramps at Denny Way.

7 **Exhibit 4-27. Transit Routes Using SR 99/Alaskan Way Viaduct South of Downtown**

3 In addition, an extensive network of bus routes converges on downtown Seattle
 4 from I-5 and via surface streets. In general, bus routes are oriented north-south,
 5 using First, Second, Third, Fourth, and to a lesser extent, Fifth Avenues. In
 6 addition, a number of express routes from Seattle neighborhoods and nearby
 7 communities use the Downtown Seattle Transit Tunnel, located beneath Third
 8 Avenue and Pine Street. As of July 2009, bus operations in the tunnel are mixed
 9 with Link light rail trains. Bus routes in the tunnel may be accessed from the
 10 International District Station (S. Jackson Street at Fifth Avenue), Pioneer Square
 11 Station (Third Avenue at Cherry Street), University Street Station (Third Avenue
 12 at University Street), Westlake Center (Pine Street at Fifth Avenue), or
 13 Convention Place Station (Pine Street at Ninth Avenue).

14 Most transit service operating on east-west streets in the downtown area
 15 (including James Street, S. Jackson Street, Yesler Way, Marion Street, Madison
 16 Street, Spring Street, Seneca Street, Pike Street, and Pine Street) is oriented to
 17 provide service between downtown and the Capitol Hill/First Hill neighborhoods
 18 or uses those streets for short segments only as part of a larger north-south
 19 oriented route.

20 Other agencies providing bus service within the study area are Sound Transit and
 21 Community Transit. These transit agencies provide more commuter-oriented
 22 services in that they operate several peak-only express services to downtown
 23 Seattle from outlying cities and neighboring counties. Sound Transit provides
 24 service to cities throughout the region in Snohomish, King, and Pierce Counties,
 25 while Community Transit provides commuter service to downtown Seattle from

1 Snohomish County. These transit providers operate routes that access downtown
2 on I-5 or I-90. Other than King County Metro, none of the region's transit
3 agencies uses SR 99 within the study area.

4 **Vanpools**

5 The transit agencies in the region all operate vanpool programs, with King
6 County Metro's being the nation's largest public vanpool program. Under
7 Metro's program, the transit agency provides and maintains a vehicle, provides
8 ride-matching service and support, and in turn collects a fee from vanpool users
9 to cover expenses. As of September 2009, approximately 40 of Metro's active
10 vanpools serve destinations in downtown Seattle, including the CBD, First Hill,
11 South Lake Union, and SODO. Vanpools are dependent on the regional highway
12 system, including HOV facilities where available, as well as local streets for
13 mobility.

14 **Link Light Rail Service**

15 The Central Link light rail line opened with the 13.9-mile segment from Westlake
16 Station to Tukwila International Boulevard Station beginning service in July 2009.
17 This line serves downtown Seattle, the SODO industrial area, the Beacon Hill and
18 Rainier Valley neighborhoods, and Tukwila. Between the International District
19 Station and the terminus at Westlake Station, light rail trains operate along with
20 bus routes in the Downtown Seattle Transit Tunnel. A fare-free shuttle bus
21 service connects the Tukwila Link Station with Sea-Tac Airport. The 1.7-mile
22 extension to Sea-Tac Airport is scheduled to open in late 2009.

23 The light rail trains offer two-way service for 20 hours each day, running every
24 7.5 minutes during peak periods and every 10 to 15 minutes during midday and
25 evening hours. Each train has two cars, each of which can carry about 200 riders.

26 **Souder Commuter Rail Service**

27 Sound Transit's commuter rail line, Souder, serves commuters north and south
28 of Seattle. The south line travels between Tacoma and King Street Station in
29 downtown Seattle and serves the communities of Puyallup, Sumner, Auburn,
30 Kent, and Tukwila. The north line travels between Everett and King Street
31 Station with a stop in Edmonds. Park-and-ride facilities in these communities
32 further extend the effective reach of the service.

33 Currently, Souder operates seven commuter trips between Tacoma and Seattle
34 during the morning (into Seattle) and evening (out of Seattle) commute periods
35 on weekdays. Also, two reverse commute trips operate during the morning (out
36 of Seattle) and evening (into Seattle). Four Souder trains operate between
37 Everett and Seattle each day as well, traveling to Seattle in the morning, and

1 returning to Everett in the evening. Occasional weekend or extra trips for special
2 events such as Mariners or Seahawks games also operate.

3 King Street Station interfaces with several other forms of transportation,
4 including the waterfront streetcar and Downtown Seattle Transit Tunnel. The
5 Weller Street Pedestrian Bridge provides a direct connection between Sounder
6 service and the Downtown Seattle Transit Tunnel.

7 **Waterfront Streetcar**

8 Improvements to downtown Seattle’s north waterfront area, including
9 construction of the Olympic Sculpture Park and work on the northern end of the
10 seawall, have necessitated the temporary suspension of the George Benson Line
11 Waterfront Streetcar vintage trolley service. King County Metro has provided
12 replacement service with free bus service on Route 99 Waterfront Streetcar Line
13 buses. Bus routing and stop locations do not exactly duplicate the Waterfront
14 Streetcar; however, Route 99 serves the same neighborhoods—the waterfront,
15 Pioneer Square, and Chinatown/International District.

16 King County Metro is currently working on plans to restore the Waterfront
17 Streetcar to active service. The project is dependent on many factors, including
18 construction of a new maintenance facility and the final alternative selected for
19 the Alaskan Way Viaduct Replacement Project.

20 The streetcar is popular with tourists and visitors, but also provides access to
21 downtown activities and businesses located in the central waterfront area,
22 International District, Pioneer Square, and Pike Place Market. It also interfaces
23 with several other transportation modes, including the Downtown Seattle Transit
24 Tunnel at the International District Station and the Seattle Ferry Terminal at
25 Colman Dock. A number of King County Metro bus stops are located near the
26 streetcar stations, as are pedestrian facilities such as the Bell Street and Marion
27 Street Pedestrian Bridges. The current service function is to serve pedestrians to
28 some of the cultural, recreational, and shopping attractions within the Seattle
29 waterfront area.

30 **South Lake Union Streetcar**

31 The South Lake Union Streetcar began operation in 2007. It provides access to
32 businesses, residences, and activities in South Lake Union and the northern part
33 of the CBD. The new streetcar line runs from Fairview Avenue N./Yale
34 Avenue N. to Westlake Avenue/Olive Way and includes 11 stops. The streetcars
35 run approximately every 15 minutes and 7 days a week. The streetcar connects
36 with several other public transportation modes, including Metro and Sound
37 Transit buses, light rail transit (Westlake Station), and the Monorail.

1 4.4.3 Transit Connectivity and Coverage

2 Transit Connections

3 In-bound express bus routes serving West Seattle and Burien use SR 99, entering
4 or exiting downtown at the Seneca Street off-ramp or Columbia Street on-ramp.
5 Because the first downtown stop for these routes is at First Avenue and Union
6 Street, many riders who need to reach the southern portion of downtown must
7 transfer to other services to backtrack southbound.

8 All bus transit serving northwest Seattle by way of SR 99 enters or exits the
9 downtown at the Denny Way ramps. From there, a number of surface streets
10 provide access into the downtown area.

11 Currently, all transit service on SR 99 in the study area exits the corridor to access
12 downtown Seattle. Transit using SR 99 from West Seattle or points south accesses
13 the downtown area at the Seneca and Columbia Street ramps. These ramps
14 provide fast service to the retail core, but passengers must transfer to other buses
15 or walk to reach offices or other destinations in the southern portion of
16 downtown.

17 There is no direct access to the viaduct to and from the north in downtown
18 Seattle, so transit routes serving the north end access SR 99 from Denny Way,
19 Battery Street, or north of Denny Way from Dexter Avenue N. or Fifth Avenue N.

20 Transit Travel Times and Coverage Area

21 All transit routes that use the SR 99 corridor access downtown at the Denny Way
22 ramps to the north, or the Columbia and Seneca Street ramps downtown. Since
23 HOV or transit-only facilities are not provided on the corridor, transit routes are
24 subject to the overall operating conditions and performance of SR 99. As
25 mentioned in the previous section, transit services serving downtown have direct
26 access into the area at Seneca and Columbia Streets, but are not able to effectively
27 provide access to the southern portions of downtown or the Pioneer Square and
28 stadium areas.

29 4.5 Freight

30 The state of Washington classifies freight routes according to the number of tons
31 of cargo carried on them. Only state routes are classified this way. Truck freight
32 tonnage on Interstate and State Routes is shown in Exhibit 4 29.

1 **Exhibit 4-29. Freight Tonnage Designations for State Routes**

Interstate/State Route	Segment	Classification
I-5	Oregon border to just south of Canadian border	T-1
I-5	Express Lanes	T-1
I-90	SR 519 to I-5	T-1
I-90	I-5 to Idaho border	T-1
SR 99	First Avenue S. Bridge to Elliott Avenue	T-1
SR 99	North of Elliott Avenue	T-2
SR 99	Alaskan Way Viaduct	T-1
SR 519	I-90 to First Avenue S.	T-2
SR 519	First Avenue S. to Seattle Ferry Terminal	T-2
SR 509	Sea-Tac to Seattle	T-2
SR 599	I-5 (Tukwila) to SR 99	T-1

2 Source: WSDOT Freight and Goods Transportation System Update, 2007.

3 Classification:

4 T-1 more than 10 million tons per year.

5 T-2 4 million to 10 million tons per year

6
 7 The City of Seattle designates all principal arterials as truck streets and has also
 8 classified certain streets as Major Truck Streets. By policy, the City will “monitor
 9 these streets and make operating, design, access and/or service changes, as well as
 10 capital investments, to accommodate trucks and to preserve and improve
 11 commercial transportation mobility and access on these major truck streets.”
 12 Seattle’s Major Truck Streets within the study area are shown in Exhibit 4 30.
 13 SR 99 is designated as a Major Truck Street, as are all or portions of 15th Avenue
 14 W., Elliott Avenue, Western Avenue, Broad Street, E. Marginal Way, First Avenue
 15 S., Fourth Avenue S., Sixth Avenue S., Airport Way S., S. Spokane Street, S.
 16 Lander Street, S. Royal Brougham Way, and Alaskan Way.

17 **4.5.1 Weight Restrictions**

18 Following the Nisqually earthquake of February 2001, weight restrictions were
 19 established to prohibit vehicles over 10,000 pounds from using the two left lanes
 20 on each level of the viaduct. These restrictions remain in place today. These
 21 restrictions also limit the use of the southbound exit to First Avenue S., which is
 22 located on the left side of the roadway. Further deterioration of the viaduct
 23 structure could lead to further restrictions.

Legend

- Major Truck Streets
- Downtown Traffic Control Zone

Exhibit 4-30
City of Seattle Designated
Major Truck Streets

4.5.2 Alternative Truck Routes in the AWW Corridor

In case of congestion, incidents, or lack of access to the Alaskan Way Viaduct, different trucks have different alternative route options. Oversized or overweight trucks are limited to the designated over-legal route along Alaskan Way and Broad Street, or I 5. Trucks larger than 27 feet are precluded from using city streets in the downtown area north of S. King Street from 6:00 a.m. to 6:00 p.m. daily, and therefore have the same options to use Alaskan Way and Broad Street or I 5 instead of the viaduct. The downtown traffic control zone is shown in Exhibit 4-30. Trucks 27 feet or smaller have the option to divert to city streets to get through the downtown area.

The Alaskan Way surface street has some drawbacks as a truck route. Truck traffic may be perceived to detract from increased waterfront and residential uses, including condominiums and sightseeing, and these uses reduce speeds and reliability for trucks along this route. Alaskan Way also contains a high number of signalized intersections along the central waterfront, which reduces travel speeds for trucks and increases potential conflicts with high volumes of pedestrians and bicyclists.

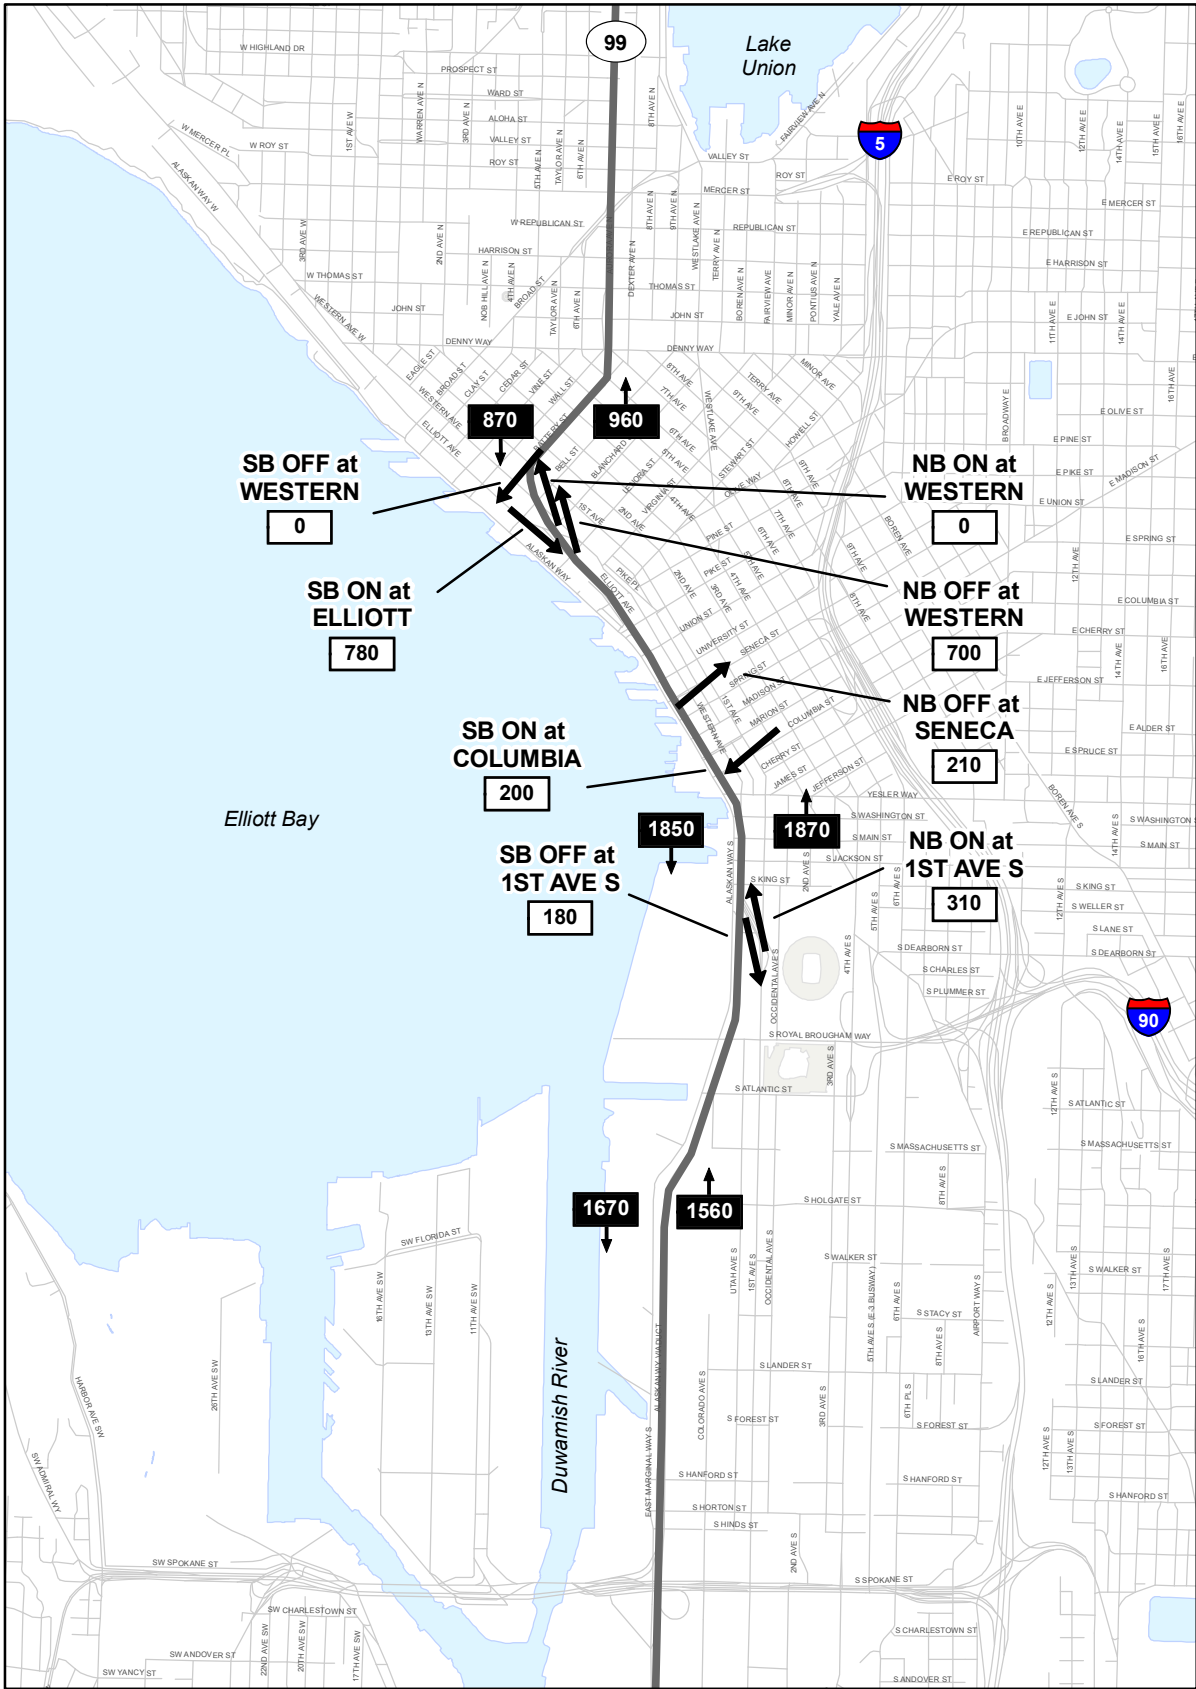

I-5 also presents challenges to truckers passing through downtown Seattle. Heavy congestion persists for much of the day. Frequent on- and off-ramps and heavy entering and exiting volumes make truck travel particularly difficult and require trucks to change lanes frequently to make a through movement. The Port of Seattle has identified access to and from the north on I-5 as an important issue resulting from congestion and poor operations on I-5 through downtown Seattle.

4.5.3 Freight and Commercial Traffic

Truck volume and classification counts were collected by video along the SR 99 corridor in downtown Seattle in June 2006. An estimated 3,720 trucks use the Alaskan Way Viaduct through central Seattle on a typical weekday (see Exhibit 4-31). This includes single-unit trucks, combination trucks, and tanker (liquid transport) trucks. Garbage trucks and concrete trucks were classified as single-unit trucks. Based on comparisons to previously collected data, the confidence level in this revised estimate is high.

Travel Patterns

South of downtown, 10 percent of southbound trucks (180 trucks) exit the corridor, and 17 percent of northbound trucks (310 trucks) enter the corridor at the First Avenue S. ramps. The lower southbound ramp volumes may be partially due to weight restrictions currently in place for the southbound outside

XXX Ramp Volumes

XXX SR 99 Mainline Volumes

Exhibit 4-31: Daily Truck Volumes Using the Alaskan Way Viaduct

1 lane, which limits access to the left-side off-ramp. Note, however, that mainline
2 truck volumes are balanced (1,870 northbound and 1,850 southbound), which
3 could indicate that trips displaced from the southbound off-ramp by these weight
4 restrictions may be continuing to use the corridor, but exiting farther to the south.
5 The majority of truck trips south of downtown continue south to E. Marginal Way
6 or West Seattle/Harbor Island.

7 North of downtown, the Elliott/Western ramps provide access to the Ballard/
8 Interbay industrial areas (by way of 15th Avenue N.W.), as well as other areas
9 northwest of downtown. A large share of truck traffic uses the Elliott/Western
10 ramps, though a majority of trucks continue north on SR 99 through the Battery
11 Street Tunnel. A smaller share of traffic accesses downtown directly using the
12 Seneca Street and Columbia Street ramps.

13 Northbound, 11 percent of trucks (210 trucks) exit SR 99 at Seneca Street,
14 37 percent (700 trucks) exit to Western Avenue, and 51 percent (960 trucks)
15 continue through the Battery Street Tunnel. Southbound, 47 percent of trucks
16 (870 trucks) access the viaduct through the Battery Street Tunnel, 42 percent
17 (780 trucks) by way of the Elliott Street on-ramp, and 11 percent (200 trucks) use
18 the Columbia Street on-ramp.

19 Classification of Truck Types

20 The composition of trucks on the viaduct along the central waterfront is
21 approximately 88 percent single-unit trucks, 9 percent combination trucks, and
22 3 percent tanker trucks (single and combination units). A higher share of
23 combination and tanker trucks use the Elliott/Western corridors, hence the
24 composition in the Battery Street Tunnel is 93 percent single units, 6 percent
25 combination trucks, and 1 percent tankers.

26 Tanker/Liquid Transport Trucks

27 Between 80 and 100 tanker trucks are estimated to use the SR 99 corridor each day
28 (40 to 50 per direction). The share of these trucks that are hauling combustible or
29 flammable materials is unknown. However, approximately 15 percent of tankers
30 on the viaduct were observed using the Battery Street Tunnel, where flammable
31 and combustible materials are prohibited. An additional 15 percent of tanker
32 trucks use the viaduct during times when flammable and combustible cargos are
33 prohibited anywhere on the viaduct: between 7:00 and 9:00 a.m., and between
34 4:00 and 6:00 p.m. Up to 70 percent of the observed tanker truck volumes—55 to
35 70 tankers per day—could therefore be legally carrying flammable or hazardous
36 loads on the viaduct.

1 Hourly Truck Volumes

2 Unlike overall traffic volumes, which peak during the morning and evening
3 commutes, truck volumes peak during the midday and afternoon. Exhibit 4 32
4 shows hourly truck volumes on the viaduct between the First Avenue S. ramps
5 and Columbia/Seneca Street ramps (this is the busiest segment of the corridor).
6 Northbound truck volumes are quite steady, generally ranging between 100 and
7 150 trucks per hour between 6:00 a.m. and 8:00 p.m. They peak at 155 trucks per
8 hour between 2:00 p.m. and 3:00 p.m. Southbound truck traffic peaks more
9 sharply (higher volumes, but for fewer hours). Southbound truck volumes don't
10 reach 100 trucks per hour until 9:00 a.m., and fall below that threshold by 6:00
11 p.m. Peak volumes do, however, range from 150 to 200 trucks per hour between
12 11:00 a.m. and 5:00 p.m., peaking at 205 trucks between 3:00 p.m. and 4:00 p.m.
13 Use of the viaduct by trucks at other times is low.

14 Exhibit 4-32. Hourly Truck Volumes on the Alaskan Way Viaduct (Midtown)

15

16

1 **Freight Access**

2 The project corridor serves areas that generate substantial freight and truck
3 traffic. Exhibit 4 33 shows the boundaries of the Duwamish/SODO
4 manufacturing and industrial area and the Ballard Interbay Northend
5 Manufacturing and Industrial Center (BINMIC), as determined by the City of
6 Seattle.

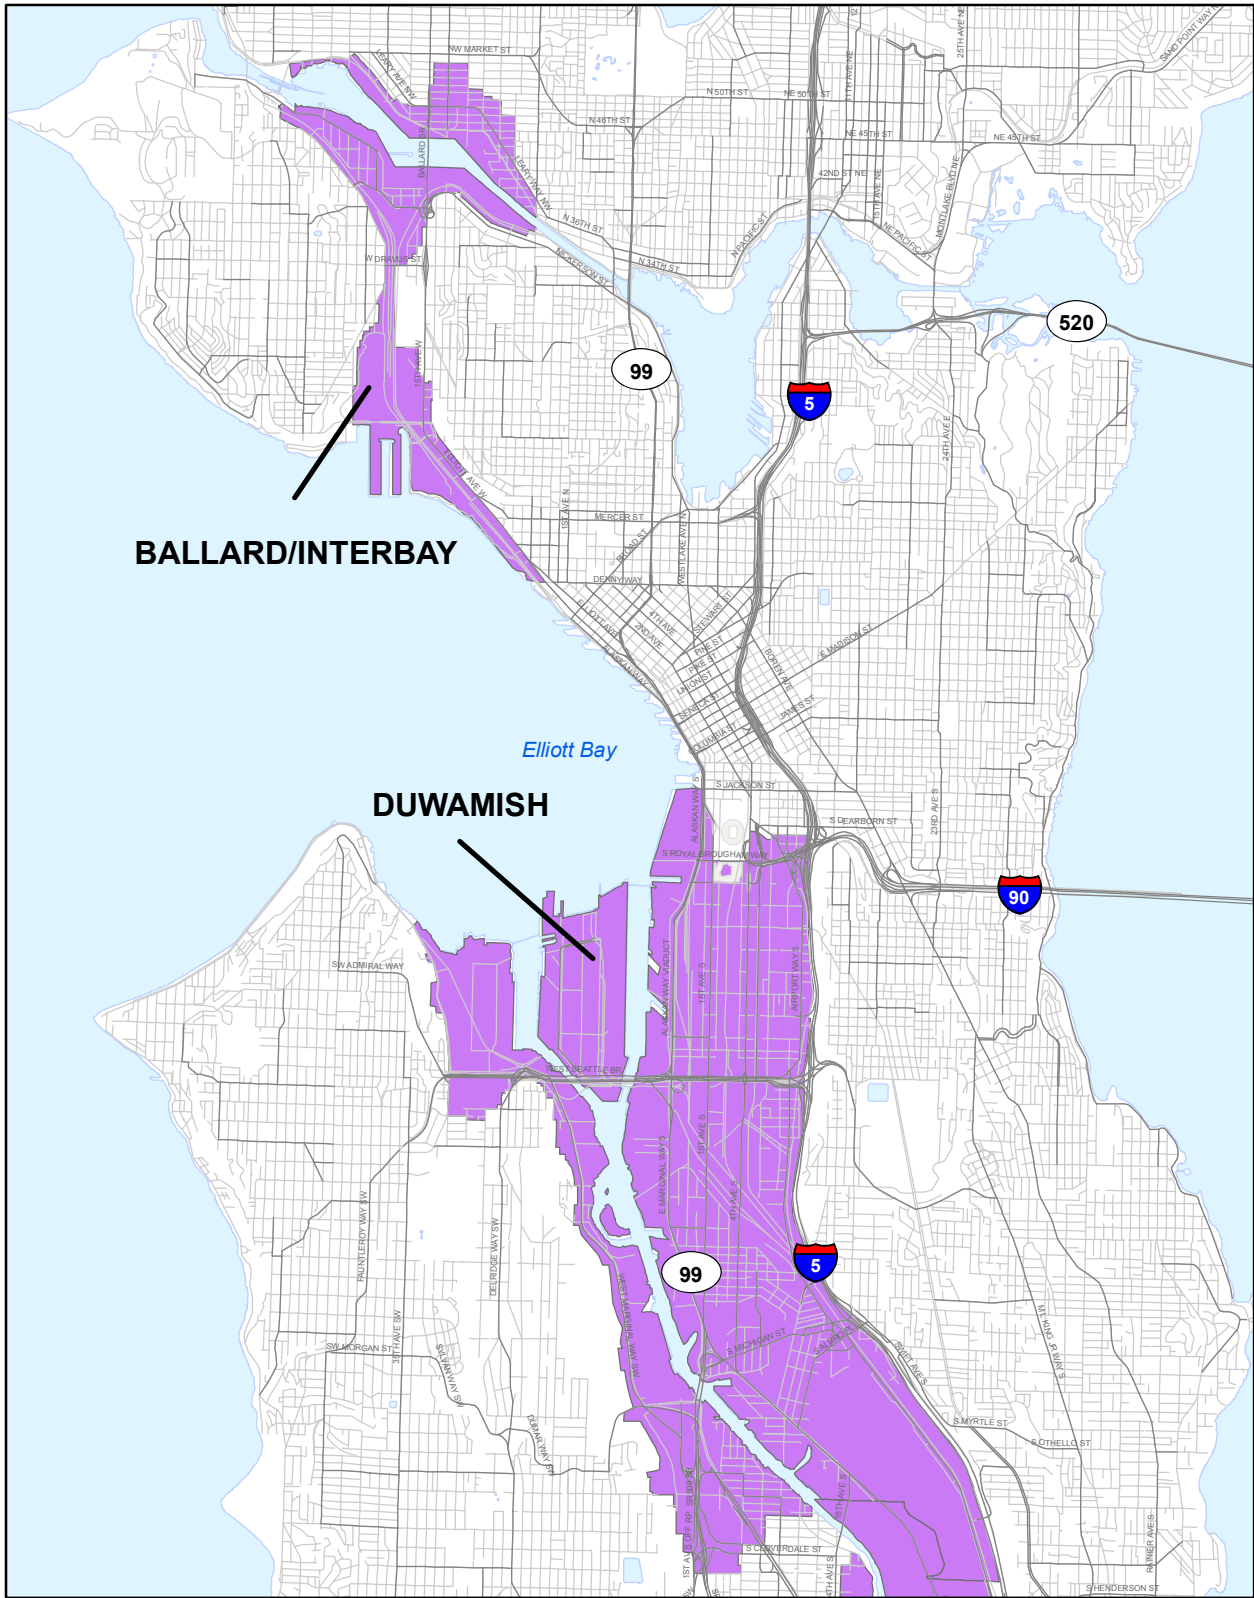

7 The southern portion of the study area falls within the Duwamish/SODO
8 manufacturing and industrial area. In addition, freight using the viaduct is often
9 destined for the BINMIC area. Light industrial and warehouse uses north and
10 south of downtown Seattle also generate substantial truck traffic. Historically,
11 freight-related businesses have clustered north and south of downtown Seattle to
12 be near both marine and railroad access.

13 In addition to the industrial areas, trucks using the project corridor are destined
14 to consumer markets throughout the city and the region.

15 Ballard Interbay Northend Manufacturing and Industrial Center

16 The BINMIC area comprises 866 acres, with over 650 businesses employing
17 approximately 14,500 employees in 2008 (City of Seattle 2009b). Many of these
18 businesses are located in this area due to its marine access. Commercial fishing
19 and marine-related businesses such as ship repair are located here. In 2005,
20 31 percent of employment in the BINMIC was in manufacturing; 14 percent in
21 wholesale trade (including warehousing), transportation, and utilities; and
22 13 percent in construction/resources (including fishing). Most BINMIC
23 businesses are small businesses employing 40 or fewer employees. Rail access is
24 provided at the BNSF Balmer Yard. The Port of Seattle also has facilities in the
25 area at Terminals 86 and 91 and Fishermen’s Terminal.

26 The BINMIC area is not served directly by the regional highway system. The
27 primary access to regional freeways and industrial areas south of Seattle is via
28 15th Avenue W., connecting to SR 99 by way of the Elliott Avenue and Western
29 Avenue ramps. Alternative routes include 15th Avenue W. or Nickerson Street
30 and Westlake Avenue N. to N. Mercer Street and I-5; however, Mercer Street and
31 I-5 provide a less direct and more congested route during most workdays.
32 Freight generators in Ballard also use arterial east-west streets in Ballard and
33 Fremont to access SR 99, including Leary Way and N. 39th Street, which is not
34 designated as a Major Truck Street by the City of Seattle.

BALLARD/INTERBAY

DUWAMISH

Basemap Data Source: City of Seattle, 2006.

**Exhibit 4-33
Ballard/Interbay and Duwamish
Manufacturing and Industrial Areas**

1 Duwamish Industrial Area

2 The Duwamish Manufacturing and Industrial Center stretches over 3,981 acres
3 from the area south of downtown Seattle, following the Duwamish River to
4 unincorporated King County south of the Seattle city limits. It includes Boeing's
5 Plant 2, much of the Port of Seattle, and almost 1,900 businesses just within the
6 city of Seattle. In 2008, approximately 65,300 employees worked in the
7 Duwamish Manufacturing and Industrial Center (City of Seattle 2009b).

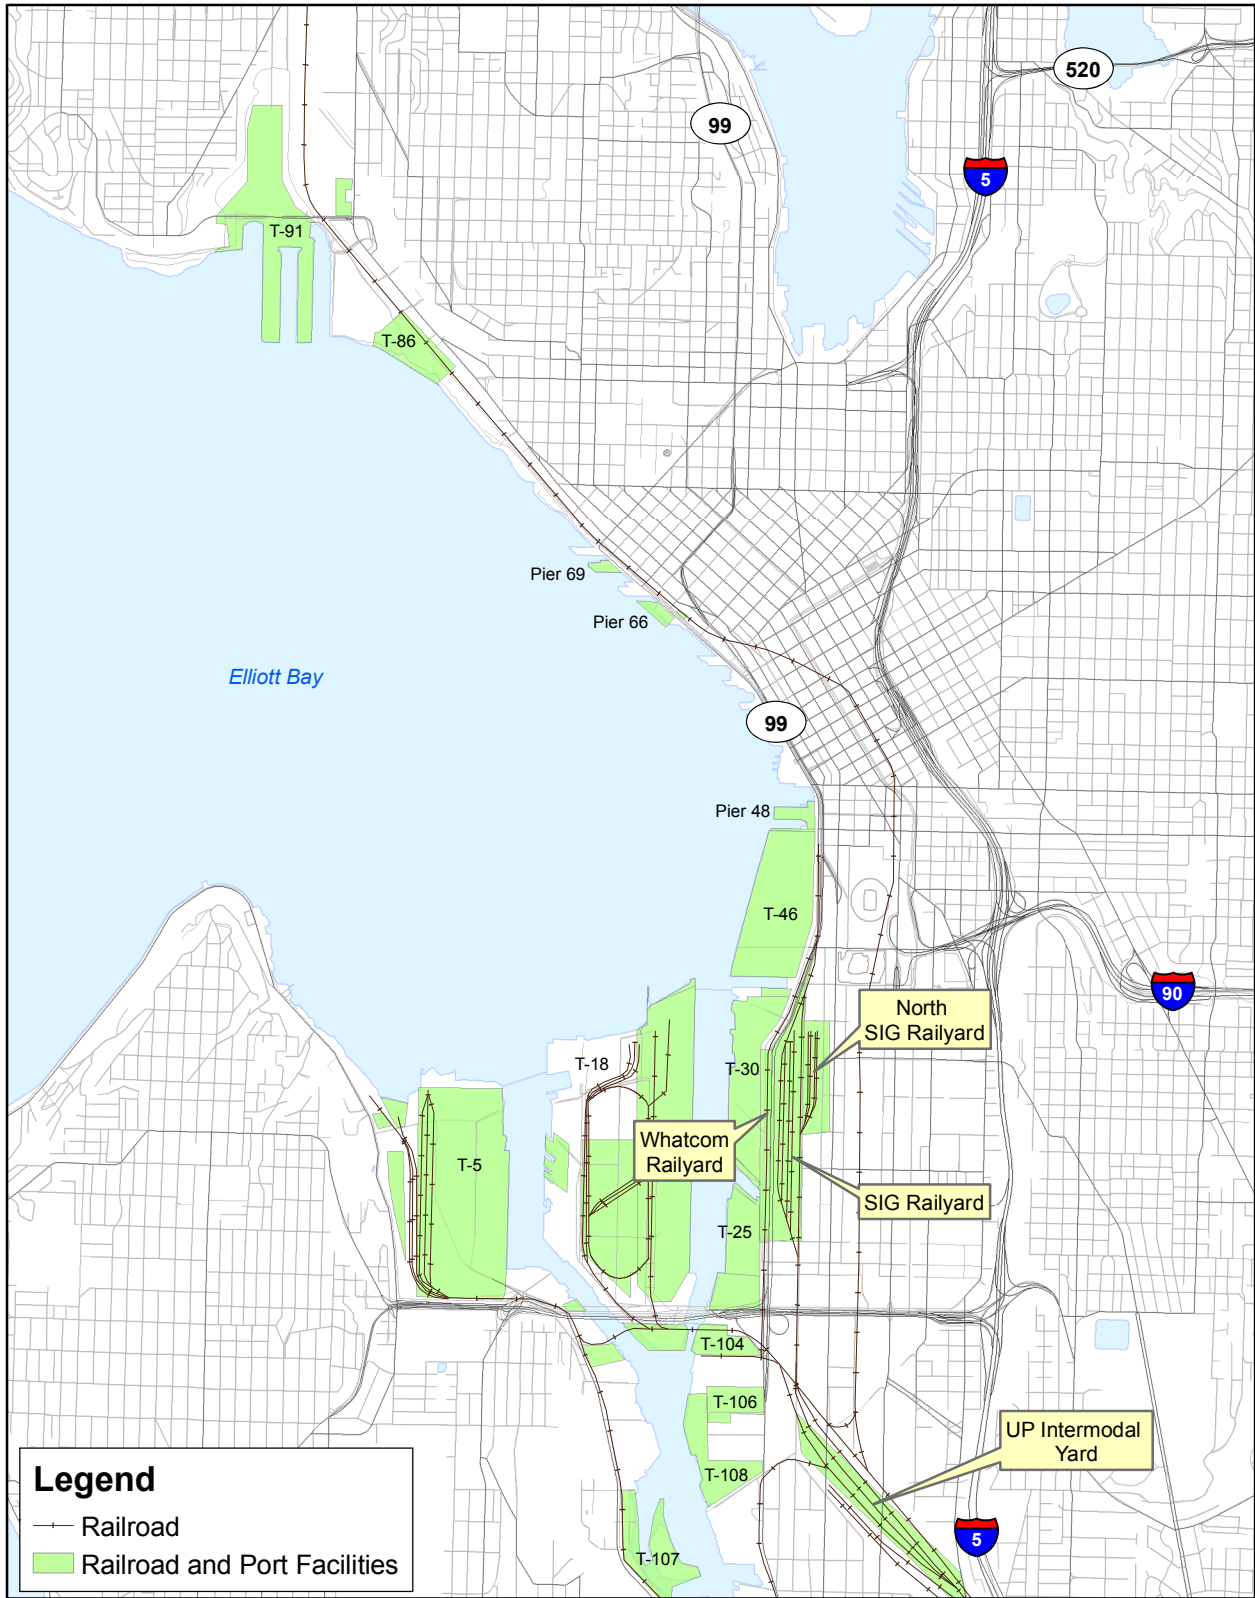

8 Marine access to the Duwamish industrial area is provided through the Port of
9 Seattle and along the Duwamish Waterway. Railroad access is provided at the
10 SIG and UPRR Argo Railyards. As described in Section 4.2.8 *Railroads*, the North
11 SIG Railyard became operational in 2008.

12 Highway access from this area to I-5 is provided by SR 519 from Fourth Avenue S.,
13 at S. Spokane Street from Sixth Avenue S. and the S. Spokane Street surface route,
14 and at Industrial Way. Alternative access routes to I-5 south include SR 99 to
15 SR 599, SR 99 to SR 509 and SR 518, and Airport Road S. Access to I-90 is provided
16 from Fourth Avenue S. at SR 519 or from S. Spokane Street and from I-5 to I-90.

17 Freight trips in the North Duwamish area, including port-related trips, must
18 share the street system with other uses, including stadium event and ferry access
19 traffic—both of which can overwhelm the street network at times. Roads and rail
20 lines intersect at many locations, and rail traffic preempts use of the roadway
21 when train activity is present. Because trains are assembled at rail switching
22 yards in the area, some train activity consists of switching movements that can
23 block intersections for an extended time. This causes truckers to rely heavily on
24 existing grade-separated facilities to avoid conflicts with rail or heavy traffic
25 conflicts. These facilities include the Alaskan Way Viaduct, the Spokane Street
26 Viaduct, and overpasses on Airport Way S., First Avenue S., and Fourth
27 Avenue S. Phase 1 of the SR 519 Intermodal Access Project added a new grade
28 separation at S. Atlantic Street to provide grade-separated access in the eastbound
29 direction between First Avenue S. and Fourth Avenue S., I-90, and I-5. Phase 2 of
30 the SR 519 Intermodal Access Project would add a corresponding westbound
31 connection by 2010.

32 Port of Seattle and Intermodal Railyards

33 The Port of Seattle is one of the largest west coast cargo centers, serving as the
34 entry and exit point for marine cargo to and from the Pacific Rim and Alaska.
35 Exhibit 4 34 shows Port of Seattle facilities, including marine cargo terminals at
36 Harbor Island and the SW Harbor (Terminals 5 and 18), along Alaskan Way in the
37 SE Harbor (Terminals 25, 30, 37, and 46), and in the Interbay area north of the
38 study area (Terminals 86 and 91). The BNSF and UPRR intermodal railyards are
39 also shown.

Basemap Data Source: City of Seattle, 2006. Port of Seattle, 2008.

**Exhibit 4-34
Port and Rail Facilities**

1 Most of the freight shipped through the port is in intermodal containers that are
2 transferred to or from railcars or trucks on the dock. Terminals 5 and 18 have
3 been upgraded over the past decade to include on-dock rail facilities. Some of the
4 containers are shuttled (called “drayed”) by truck to or from the BNSF or UPRR
5 intermodal railyards to be transferred to or from railcars remotely.

6 Trucks entering or leaving Terminals 5 and 18 use the S. Spokane Street viaduct to
7 reach I-5, but use surface-level S. Spokane Street to get to and from Duwamish
8 locations since there are no connections from the S. Spokane Street viaduct to the
9 south on SR 99.

10 Terminals located along SE Harbor do not have on-dock rail facilities, and when
11 ships are unloaded at these terminals, those containers bound inland by rail must
12 be drayed between the terminal and the railyard. The primary dray route is along
13 E. Marginal Way to S. Atlantic Street, under the Alaskan Way Viaduct to the
14 north entrance of the BNSF SIG Railyard. Other key truck arterials in the north
15 Duwamish area include W. Marginal Way, Alaskan Way, and S. Michigan and
16 S. Hanford Streets.

17 Bulk (non-containerized) grain shipments are made through Terminal 86, and
18 generally these loads arrive and leave via rail rather than by truck. Bulk cargo
19 also passes through Terminal 91, often as oversized vehicle loads that must use
20 designated over-legal routes to reach their landside destinations. Alaskan Way
21 surface street, Broad Street, and 15th Avenue W. are the designated over-legal
22 route to and from the Interbay area.

23 Truck arrivals at port gates are constant between 8:00 a.m. and about 3:30 p.m.,
24 with few arrivals during the noon hour when gate employees take lunch break.
25 Port gate operation determines when trucks can arrive and leave, including the
26 hours when the gates open and close and when employee breaks are observed.

27 Freeway access to and from I-5 and I-90 are provided at SR 519 and at S. Spokane
28 Street from both the viaduct level and the surface roadway. Access to I-90 from
29 S. Spokane Street requires entering and exiting from I-5 in a bottleneck location.
30 Since I-5 is congested during much of the work day, alternate access to and from
31 I-5 is provided using SR 509 and SR 518, SR 99 and SR 599, or Airport Way S.

32 4.5.4 Railroads

33 BNSF maintains two mainline tracks through the study area, paralleling I-5 to the
34 south and running between First and Fourth Avenues S., crossing S. Spokane
35 Street, S. Lander Street, S. Holgate Street, and S. Royal Brougham Way (SR 519)
36 at-grade. North of S. Royal Brougham Way is the King Street Station and a tunnel
37 under the downtown area that emerges north of the Pike Place Market and
38 follows the waterfront to points north. This route serves the Interbay switching

1 and engine maintenance and refueling yard. The BNSF mainline serves the I-5
2 corridor south to Long Beach and north to British Columbia, connecting to east-
3 west tracks crossing the Cascades at Everett, Auburn, and along the Columbia
4 River. BNSF has agreements with the state, Amtrak, and Sound Transit to carry
5 intercity and regional commuter rail passenger trips that are accessed at King
6 Street Station. Passenger train switching and staging occur on switching tracks
7 north and south of SR 519.

8 UPRR maintains a single mainline track heading south from Seattle, using a
9 shared alignment with BNSF until Tukwila. UPRR also serves the I-5 corridor
10 and connects to east-west tracks at the Columbia River. The UPRR Argo
11 intermodal switching yard is south of S. Spokane Street. Capacity of the
12 combined UPRR and BNSF tracks is reduced due to operational conflicts caused
13 by the need for UPRR trains to cross the BNSF mainline to access the Argo
14 Railyard. Both the UPRR and BNSF tracks serving Terminals 5 and 18 cross
15 E. Marginal Way at-grade, creating delays for heavy truck traffic in that area.

16 SIG and Whatcom Railyard Operations

17 The BNSF SIG Railyard is located on the east side of SR 99, south of S. Atlantic
18 Street. This intermodal yard is used to load cargo containers (most of which
19 arrive by sea at the port facilities on the west side of SR 99) onto railcars, and
20 switch railcars to build freight trains. A switching track, termed the tail track,
21 extends north from the SIG Railyard, crossing S. Atlantic Street and S. Royal
22 Brougham Way. Switching operations at the SIG Railyard frequently block these
23 streets near their intersections with Alaskan Way.

24 As part of the S. Holgate Street to S. King Street Viaduct Replacement Project, a
25 grade separation from the BNSF tail track will be provided by a U-shaped
26 depressed roadway that extends from the S. Atlantic Street/Colorado Avenue S.
27 intersection to the S. Atlantic Street/E. Marginal Way S. intersection. The aerial
28 mainline structure and depressed local street would combine to provide both at-
29 grade and grade-separated access across the BNSF tail track.

30 Two additional BNSF tracks pass through the Whatcom Railyard on the west side
31 of SR 99. One track used for train assembly continues from the SIG Railyard
32 north across S. Royal Brougham Way just west of the viaduct, causing backups
33 for trucks accessing Port terminals along the waterfront.

34 4.6 Parking

35 4.6.1 Parking Space Definitions

36 This assessment quantifies “public parking,” unless otherwise noted. Public
37 parking is defined as (1) parking spaces regulated by the City and (2) pay parking

1 lots from which money is collected by a private entity but parking spaces are
2 available to the public. Parking was grouped and summarized into three main
3 categories of on-street short-term, on-street long-term, and off-street parking.
4 Viaduct demolition poses a special case where restricted parking spaces are
5 discussed.

6 **On-Street Short-Term Parking**

7 Existing short-term parking includes metered spaces (including pay stations) with
8 up to a 2-hour limit; passenger and commercial loading zones; and taxi, bus, and
9 police parking.

10 **On-Street Long-Term Parking**

11 On-street long-term parking includes 10-hour metered spaces plus unmetered,
12 unrestricted, on-street public parking. These types of spaces are found in the
13 south end of the project area under the viaduct and in the south portal area.

14 **Off-Street Parking**

15 Off-street parking includes privately owned parking lots at which the public can
16 park for a fee. In most cases, public parking does not include private business
17 customer or employee parking. The exception is some parking under the viaduct
18 that is restricted during daytime hours on weekdays but used as public parking at
19 other times.

20 **Restricted Parking**

21 As noted previously, this assessment quantifies “public parking.” However,
22 viaduct demolition would affect some restricted parking spaces under the
23 viaduct, along the west side of buildings and loading docks. These spaces can
24 generally be categorized as restricted or reserved for private business use,
25 including customer and employee parking, but some of the spaces can be used by
26 the public during non-business hours. The effect of viaduct demolition on
27 restricted spaces is noted in Chapter 6, Construction Effects and Mitigation,
28 Section 6.1.8, Parking.

29 **4.6.2 Parking Study Boundaries**

30 The parking study was generally limited to the areas that are within the urban
31 design boundary for surface street improvements. The parking assessment areas
32 are organized according to south portal, central, and north portal areas. Only the
33 south and north portal areas are associated with the final configuration of the
34 project. The central area is discussed in the context of construction and the larger
35 Program and viaduct demolition activities.

1 Potential parking effects were estimated for the Bored Tunnel Alternative. The
 2 plans for surface street improvements, submitted with the Alaskan Way Viaduct
 3 Replacement Project configuration drawings (July 2009), were used as a guide for
 4 on-street parking lanes and affected off-street parking areas.

5 4.6.3 Existing Parking Spaces

6 Exhibit 4 35 summarizes the existing parking in the study area. By definition, the
 7 parking study areas were delineated to quantify parking in the vicinity of SR 99
 8 and Alaskan Way that would be affected by the project.

9 Near the south portal, about 180 on-street spaces and 250 off-street spaces are
 10 within the surface street improvement boundary. In the north portal area, about
 11 330 on-street spaces are within the surface street improvement boundary, about
 12 half of which are 10-hour metered spaces. Approximately 40 off-street spaces in
 13 public pay lots are also within the surface street improvement boundary.

14 Parking spaces in the central area, under the viaduct and along Alaskan Way
 15 from S. King Street to Pine Street, would only be affected during viaduct
 16 demolition activities.

17 Exhibit 4-35. Summary of Existing Parking Spaces

	On-Street Spaces			Off-Street Spaces	Total Spaces
	Short-Term	Long-Term	Subtotal		
South portal area	170	40	210	250	460
Central: under the viaduct and along Alaskan Way	580	10	590	435	1,025
North portal area	70	230	300	40	340

18

19 4.7 Pedestrians

20 The study area includes several noteworthy pedestrian generators:

- 21 • Two stadiums
- 22 • Major employment centers
- 23 • Major tourist attractions
- 24 • Green space/recreational areas

25 Sidewalks are found on the majority of streets in the study area and are the
 26 primary source of pedestrian access and mobility. Other pedestrian facilities in
 27 the study area include a multi-use path on the east side of Alaskan Way and
 28 pedestrian bridges across Alaskan Way at Marion Street, Lenora Street, and Bell

1 Street that link the downtown and Belltown areas with the waterfront. The
2 following discussion will provide information on pedestrian facilities for the
3 following project areas:

- 4 • South portal area
- 5 • Waterfront area
- 6 • North portal area

7 **4.7.1 South Portal Area**

8 The southern project area includes the area immediately to the west of the sports
9 stadiums and adjacent to the Port of Seattle and other industrial land uses.
10 Pedestrian activity is highly variable in the southern project area due to the mix of
11 land uses in the area and the stadiums. With sidewalks on both sides, First
12 Avenue S. and Occidental Avenue S. provide the main north-south pedestrian
13 facilities in the area; both streets have low traffic volumes and large sidewalk
14 areas adjacent to Qwest Field. Alaskan Way S. provides intermittent sidewalks in
15 this area, typically on the western edge of the roadway adjacent to the Port of
16 Seattle properties.

17 During non-event times, pedestrian traffic is relatively light along First Avenue S.,
18 Occidental Avenue S., and Alaskan Way S. However, these roadway facilities,
19 particularly those on Occidental and First Avenues S., experience significant
20 pedestrian volumes during events at either Safeco or Qwest Field. During larger
21 events, such as a Mariners baseball game or a Seahawks football game, thousands
22 of pedestrians crowd the sidewalks and alleys in the stadium and Pioneer Square
23 areas. Intersections throughout the area become saturated with pedestrian
24 activity, and both the pedestrian and traffic LOS are considerably degraded.
25 During such events, police officers typically provide traffic control to manage the
26 very high vehicle and pedestrian volumes.

27 **4.7.2 Waterfront Area**

28 The waterfront area includes Alaskan Way from S. King Street to Broad Street.
29 Primary pedestrian traffic generators along the waterfront include tourist
30 activities, businesses, recreational uses, and ferry service. The north waterfront
31 (north of Pike Street) includes two major pedestrian facilities providing
32 connections to the waterfront:

- 33 • Bell Street Pedestrian Bridge, which extends over Alaskan Way and the
34 BNSF railroad tracks and connects to the Bell Street Pier.
- 35 • Lenora Street Pedestrian Bridge, which provides access from Elliott
36 Avenue to the east side of Alaskan Way.

1 South of the existing Battery Street Tunnel portal, SR 99 is elevated as it passes
2 over local streets and pedestrian facilities. Sidewalks on these local streets
3 provide the majority of pedestrian routes between areas downtown and the
4 waterfront. Between University Street and Elliott Avenue, steep grades limit
5 east–west connections under the viaduct. The only pedestrian connection
6 between downtown and the waterfront in this area is the Lenora Street Pedestrian
7 Bridge. The viaduct structure itself is also a barrier to pedestrian travel to some
8 degree, as it is an imposing presence and creates a visual barrier between the
9 western edge of downtown and the waterfront. Its shadows, dark spaces, and
10 vehicle noise create an unfriendly pedestrian environment.

11 **Pedestrian Facilities Along Alaskan Way**

12 A widened sidewalk on the west side of Alaskan Way fronts waterfront
13 businesses and attractions, acting as a pedestrian promenade. The promenade
14 varies from 16 to 20 feet wide in the central waterfront area. The east side of
15 Alaskan Way is only periodically fronted by sidewalks between S. King Street
16 and Pike Street, primarily at stops for the waterfront streetcar. Farther north, a
17 sidewalk is provided between Pike Street and Clay Street on the east side of
18 Alaskan Way. An asphalt walkway is provided for the length of Alaskan Way on
19 the opposite (east) side of the streetcar tracks. This path is used by a mix of users,
20 including walkers and bicyclists.

21 Pedestrians cross Alaskan Way both at-grade and at two pedestrian bridges. The
22 Marion Street Pedestrian Bridge connects the Seattle Ferry Terminal to First
23 Avenue, allowing commuters and other ferry users to access downtown without
24 having to cross Alaskan Way at-grade. To the north, the Bell Street Pedestrian
25 Bridge connects to Elliott and Western Avenues. The Lenora Street Pedestrian
26 Bridge links the Belltown and north Pike Place Market area to Alaskan Way
27 (providing grade separation from SR 99 and the BNSF mainline), but does not
28 cross Alaskan Way.

29 Surface crossings of Alaskan Way are provided regularly at intersections; the
30 intersections are signalized at Yesler Way and Columbia, Marion, Madison,
31 University, Pike, Wall, and Clay Streets. Some pedestrian crossings at signalized
32 intersections may require pedestrians to travel out of direction if they are
33 unaware that there are only two crossings between Madison and Wall Streets, a
34 stretch of nearly one mile.

35 Pedestrian traffic along the waterfront experiences substantial variability—both
36 day-to-day and seasonally—due to ferry, tourist, and cruise ship activities. Data
37 from Washington State Ferries (Exhibit 4-36) show that overall foot passenger
38 volumes are typically higher during the summer months than during the fall and
39 winter months. Unlike overall pedestrian volumes in the downtown area, which

1 are generally associated with typical workday activities and tend to peak during
2 the weekday PM peak hour, pedestrian volumes along the downtown waterfront
3 tend to peak during the weekend PM peak hour in the summertime.

4 **Exhibit 4-36. Washington State Ferries Seasonal Foot Passenger Traffic at Colman Dock**

5
6 Source: Washington State Ferries, 2009.

7 **4.7.3 North Portal Area**

8 The north portal area consists of the western portion of the South Lake Union
9 neighborhood and the Uptown neighborhood. North of Denny Way, SR 99
10 divides the grid system and separates the South Lake Union area from Uptown
11 and the Seattle Center area. This segment of SR 99 is at-grade, and the only
12 pedestrian crossings provided are at Denny Way, Mercer Street, and Broad Street.

13 Denny Way and Dexter Avenue serve as the primary east-west and north-south
14 pedestrian routes, respectively. Mercer and Broad Streets also serve as east-west
15 pedestrian routes, but sidewalks on both streets are quite narrow, and these
16 streets pass under SR 99, which does not provide a comfortable or attractive
17 environment for most pedestrians.

18 Pedestrian activity in the South Lake Union area continues to increase as
19 residential, commercial, and retail development continues. Similar to the south

1 portal area, pedestrian activity increases near Seattle Center during events to
2 levels considerably higher than during non-event times.

3 4.7.4 Interaction Between Pedestrians and Vehicle Traffic

4 Pedestrians may encounter heavy traffic and fast-moving vehicles at locations
5 where traffic enters or exits SR 99. The Denny Way ramps are one location where
6 vehicles encounter pedestrians immediately as they exit the highway. These
7 ramps have sidewalks and buses along their outside lanes. This has been
8 identified by WSDOT as a high pedestrian accident location.

9 The Battery Street and Elliott Avenue/Western Avenue ramps also introduce
10 highway traffic into a pedestrian environment with little transition. At the
11 southbound on-ramp at Elliott Avenue and the northbound Battery Street on-
12 ramp, accelerating traffic entering the highway crosses pedestrian traffic traveling
13 along Western or Elliott Avenues. The northbound off-ramp to Western Avenue
14 accommodates high traffic volumes, which encounter an active pedestrian
15 environment immediately at the base of the ramp. An unsignalized crosswalk at
16 Bell Street crosses the ramp immediately as it joins the street grid. Both Western
17 and Elliott Avenues experience moderate to high levels of pedestrian activity.

18 At the southbound off-ramp to First Avenue S., pedestrians on First Avenue S. are
19 routed around the ramp structure to a narrow, hidden walkway. The Columbia
20 and Seneca Street ramps are signal controlled, and traffic is slowed to arterial
21 speeds due to sharp curves on the ramps. Still, traffic entering or exiting the
22 ramps encounters conflicting pedestrian traffic when turning on to or off of First
23 Avenue S. to access the ramps.

24 4.8 Bicycle Facilities

25 Bicycles are used in the study area both for recreational and commuting purposes.
26 This section describes existing bicycle facilities and routes, planned facilities and
27 routes, and how these facilities and routes relate to the existing SR 99 facility. The
28 following discussion will provide information on bicycle facilities for the
29 following project areas:

- 30 • South portal area
- 31 • Waterfront area
- 32 • North portal area

33 4.8.1 Bicycle Facilities and Designated Bike Routes

34 Seattle features an extensive network of bicycle facilities and routes. A
35 substantial number of commuters travel to jobs in the downtown area via these

1 routes. Sharrows are bicycle symbols that are placed in the roadway lane
2 indicating that motorists should expect to see and share the lane with bicycles.
3 Unlike bicycle lanes, they do not designate a particular part of the roadway for
4 the use of bicyclists. City of Seattle designated bicycle facilities and routes in the
5 downtown area are shown in Exhibit 4-37.

6 4.8.2 South Portal Area

7 E. Marginal Way S. is a major bicycle route near the south portal area and is a
8 regional connection that serves as the main route into and out of downtown for
9 West Seattle residents. The SR 99/E. Marginal Way corridor is recognized as
10 being the safest and primary connection for bicyclists from the West Seattle,
11 White Center, Arbor Heights, and Burien areas to the downtown CBD. This
12 corridor also serves as a key conduit to allow bicyclists access to other
13 neighborhoods and communities in the region. Recent improvements to the
14 bicycle network include sharrows on First Avenue S. between S. Lander Street
15 and S. Jackson Street.

16 4.8.3 Waterfront Area

17 Major facilities along the waterfront include the multi-use path located to the east
18 of Alaskan Way surface street, which runs from the stadium area to Myrtle
19 Edwards Park, and the multi-use trail that starts in Myrtle Edwards Park and
20 runs northward through the Interbay area to Magnolia. Bicycle facilities are not
21 presently provided on the Alaskan Way surface street, though cyclists ride either
22 in the street or on the parallel asphalt path shared with pedestrians.

23 4.8.4 North Portal Area

24 Dexter Avenue N. serves as the main northbound and southbound route for
25 bicyclists traveling between downtown and points north. Second Avenue serves
26 as the main route for bicyclists heading southbound through downtown, while
27 First, Third, and Fourth Avenues are used for northbound travel. A new bicycle
28 lane has been provided on Ninth Avenue N. between Denny Way and Republican
29 Street.

30 4.8.5 Regional Connections

31 Near the north portal area, the bicycle lane on Dexter Avenue N. connects to the
32 Fremont Bridge and the Burke-Gilman Trail, which provides regional connections
33 to Ballard, the University District, and points beyond along Lake Washington. As
34 mentioned previously, the trail in Myrtle Edwards Park leads to a trail through
35 the Interbay area to Magnolia and a trail along the south side of the Fremont cut.

* Commonly used by bicyclists

Basemap Data Source: City of Seattle, 2009.

**Exhibit 4-37
City of Seattle Designated
Bicycle Routes**

1 To the south, E. Marginal Way connects to S. Spokane Street, along which bicyclists
2 can travel to reach the low West Seattle Bridge and a multi-use trail along the water
3 around Alki Point. Near the stadiums, S. Dearborn Street connects to the I-90 Trail,
4 which provides connections to Mercer Island and beyond.

5 **4.8.6 Planned Improvements**

6 The City of Seattle adopted a Bicycle Master Plan that was approved May 22, 2007, by
7 the Seattle Bicycle Advisory Board. The plan has informed development of
8 approximately 450 miles of marked or separated bicycle routes, which will be
9 completed over the next 10 years, including multi-use trails, bicycle lanes, and
10 sharrows.

11 The Bicycle Master Plan calls for a number of improvements in the stadium area,
12 many of which will be provided as part of the S. Holgate Street to S. King Street
13 Viaduct Replacement Project, as well as this project. These two projects will construct
14 a combined bicycle and pedestrian facility adjacent to the Port of Seattle property
15 between S. King Street and S. Atlantic Street. Bicycle lanes would be incorporated
16 into the new street grid between S. King Street and the new S. Plummer Street, and
17 cyclists can also use the combined pedestrian and bicycle sidewalk/promenade
18 between S. Atlantic Street and S. Plummer Street on the new Alaskan Way S.

19 The City of Seattle's Bicycle Master Plan also calls for new bike facilities on S. Royal
20 Brougham Way from the new Alaskan Way S. to Fourth Avenue S. (on a new
21 overpass over the BNSF tracks), and on S. Holgate Street east from First Avenue S.
22 A new multi-use path is planned for S. Royal Brougham Way from Fourth
23 Avenue S. east to Beacon Hill, where it would connect with the existing Mountains
24 to Sound/I-90 Trail and a new trail that would continue south along the west side of
25 Beacon Hill.

26 In the central waterfront area, the Bicycle Master Plan includes a bicycle lane on
27 Alaskan Way with an additional bicycle lane on Western Avenue from Blanchard
28 Street to Yesler Way. In the north waterfront, a new bicycle lane is planned for
29 Alaskan Way from Broad Street to the south, and Elliott, Western, and First
30 Avenues would include sharrows.

31 In the South Lake Union area, Western and Fairview Avenues are called out as key
32 study corridors. Several planned bicycle improvements in the north portal area
33 include the Lake Union to Elliott Bay Trail (previously known as the Potlatch Trail).
34 The Lake Union to Elliott Bay Trail project is being coordinated with the City of
35 Seattle's larger Mercer Corridor project and the Mercer Street changes completed by
36 this project. Other planned improvements include a new bicycle/pedestrian
37 overpass connecting Uptown to the waterfront at Thomas Street that is currently
38 under design by the City of Seattle.

1 **4.9 Ferry Services**

2 Ferry service to downtown Seattle is provided by Washington State Ferries and
3 King County. Washington State Ferries provides direct ferry service between
4 downtown Seattle and both Bainbridge and Bremerton. Alternate transportation
5 connections between Seattle and these communities are by highway through
6 Tacoma (via the Tacoma Narrows Bridge), or by ferry to Edmonds. The King
7 County Ferry District provides service to downtown Seattle from West Seattle and
8 Vashon Island (effective September 28, 2009). Alternative transportation
9 connections for the West Seattle route involve the West Seattle Freeway and either
10 SR 99 or surface streets. Alternatives for the Vashon Island service involve
11 Washington State Ferries service to Fauntleroy and surface streets to the West
12 Seattle Bridge and either SR 99 or surface streets to downtown Seattle.

13 Colman Dock, located on Pier 50 and 52 on Seattle’s downtown waterfront, is the
14 Seattle terminus for the Washington State Ferries. The service from Vashon Island
15 also uses Colman Dock while the service from West Seattle uses Pier 55 in the
16 central waterfront. Access to Colman Dock is provided from Alaskan Way at Yesler
17 Way, and exits are provided to Alaskan Way at Yesler Way and Marion Street.

18 **4.9.1 Vehicle and Passenger Ferries**

19 For the Washington State Ferries service, two Jumbo Mark II boats, each with a
20 capacity of 202 vehicles and 2,500 passengers, operate on the Bainbridge Island
21 service between 4:45 a.m. and 1:35 a.m. daily, with departures and arrivals
22 approximately every 50 minutes. Service to Bremerton is provided by one Super
23 Class ferry, which has a capacity of 144 vehicles and 2,500 passengers and one
24 Jumbo Class ferry, which has a capacity of 188 vehicles and 2,000 passengers.
25 Bremerton service operates on an approximate 80-minute headway daily between
26 4:50 a.m. and 12:50 a.m.

27 **4.9.2 Passenger-Only Ferries**

28 The King County Ferry District service from West Seattle currently uses one boat
29 leased from Argosy Cruises. The passenger-only boat can accommodate 250
30 passengers. On weekdays, service is provided approximately each hour starting at
31 7:00 a.m. and ending at approximately 11:00 p.m. On weekends, service levels are
32 the same as weekdays except that operations start at 8:30 a.m. The West Seattle
33 ferry operates April through October. Starting in 2010, the service will operate
34 year-round.

35 Passenger-only ferries also connect downtown Seattle and Vashon Island. While
36 currently operated by Washington State Ferries, the King County Ferry District will
37 assume operations for this route effective September 28, 2009. Service is provided

1 by a vessel with a capacity of 250 people. Service departs from Pier 50 three times
2 per day.

3 4.9.3 Characteristics of Ferry-Related Traffic

4 Arterial intersection analysis estimates that 525 vehicles exit Colman Dock during
5 the AM peak hour, while 200 vehicles arrive to travel westbound during the same
6 time period. During the PM peak hour, the pattern reverses to a degree, with 360
7 vehicles exiting Colman Dock during the PM peak hour and 540 vehicles arriving at
8 Colman Dock during the PM peak hour under current conditions.

9 The analysis assumes that there is one Bremerton and two Bainbridge route
10 arrivals/departures, with the eastbound ferries at approximately 60 percent capacity
11 and the westbound ferries at about 90 percent capacity. This estimate is based on
12 existing PM peak hour demand at Colman Dock for the 30th busiest day of the year,
13 which corresponds to a 92nd percentile weekday and is of a magnitude that is
14 consistent with traffic counts taken in the vicinity of Colman Dock. Because the
15 volumes represent a typical traffic day, there are days throughout the year during
16 which even higher volumes occur.

17 Currently, offloading (eastbound) traffic cues a signal preempt that allocates up to
18 180 seconds for traffic exiting Colman Dock at either Marion Street or Yesler Way.
19 Once the preempt phase is completed, the north-south movements are allocated
20 their normal split timings. The combined splits result in very long—and
21 uncoordinated—signal cycle lengths. The preempt will continue to trigger
22 subsequent allocations of up to 180 seconds for exiting ferry traffic until the vessel is
23 empty (typically three preempt cycles). While vessels are unloading, approximately
24 70 to 75 percent of the green time is allocated to traffic exiting Colman Dock. During
25 this time, delay for Alaskan Way traffic increases substantially as ferry movements
26 are emphasized.

27 Following an unloading event, the signals will attempt to reactivate coordination
28 with neighboring signals and eventually return to normal operation. Once signal
29 recovery is achieved, the north-south flow on Alaskan Way is largely uninterrupted
30 at the Marion Street and Yesler Way cross-streets except for pedestrian or occasional
31 auto crossings. Note that the pattern of regular unloading with such a long preempt
32 often leads to essentially uncoordinated traffic operations on Alaskan Way during a
33 large share of the peak period today. The traffic models used to assess intersection
34 conditions for this EIS do not specifically model the back-and-forth preemption
35 cycles, and instead reflect an estimated “average” condition during the peak hour.
36 Therefore, LOS and delay at these locations may be somewhat understated.

1 **Passenger Connections to the Seattle CBD**

2 The majority of foot passengers arriving at or departing from Colman Dock use the
 3 larger vehicle ferries. Loading and unloading is at the upper level of Colman Dock,
 4 from which a direct walkway is provided that crosses above Alaskan Way and
 5 below the viaduct, connecting to the sidewalk on the south side of Marion Street at
 6 First Avenue. Passengers can also enter and exit at Alaskan Way, where they can
 7 catch a bus or cross Alaskan Way. Signalized crosswalks crossing Alaskan Way are
 8 located at Marion Street, Columbia Street, and Yesler Way. Conflicting traffic
 9 volumes are heavy on Alaskan Way while ferries are unloading, as traffic exits at
 10 Marion Street (to northbound and southbound Alaskan Way, as well as eastbound
 11 on Marion Street) and Yesler Way (to southbound Marion Street only). Additionally,
 12 pedestrians using the Marion Street Pedestrian Bridge can face conflicts from turning
 13 vehicles as they rejoin the street-level sidewalk system at First Avenue and Marion
 14 Street. While the intersection is signalized, exiting ferry traffic that wishes to turn
 15 right onto southbound First Avenue would face conflicting pedestrians in the
 16 crosswalk.

17 **Automobile Access and Egress**

18 Both Colman Dock access points, Alaskan Way at Yesler Way and at Marion Street,
 19 are estimated to operate at an overall average of LOS B during both the AM and PM
 20 peak hours (Exhibits 4-38 and 4-39). All major movements operate at LOS C or
 21 better during either peak. Note, however, that both the Marion Street and Yesler
 22 Way intersections experience increased congestion while ferry vessels unload, with
 23 decreased congestion at other times. The data presented here are the average for the
 24 entire AM and PM peak hours.

25 **Exhibit 4-38. Existing (2005) AM Peak Hour Average Vehicle Delay (seconds) and**
 26 **LOS by Movement at Colman Dock**

Traffic Movement	Average AM Peak Hour Conditions	
	Delay (seconds)	LOS
Marion Street	16	B
Eastbound (exiting Colman Dock)	28	C
Northbound Alaskan Way	10	B
Southbound Alaskan Way	7	A
Yesler Way	20	C
Eastbound (exiting Colman Dock)	18	B
Northbound left (entering Colman Dock)	16	B
Northbound through Alaskan Way	19	B
Southbound Alaskan Way	24	C

1 Exhibit 4-39. Existing (2005) PM Peak Hour Average Vehicle Delay (seconds) and
 2 LOS by Movement at Colman Dock

Traffic Movement	Average PM Peak Hour Conditions	
	Delay (seconds)	LOS
Marion Street	13	B
Eastbound (exiting Colman Dock)	27	C
Northbound Alaskan Way	10	A
Southbound Alaskan Way	8	A
Yesler Way	24	C
Eastbound (exiting Colman Dock)	15	B
Northbound left (entering Colman Dock)	21	C
Northbound through Alaskan Way	18	B
Southbound Alaskan Way	29	C

3 **4.10 Safety**

4 This section summarizes collision data for SR 99 within the transportation study
 5 area. The analysis was conducted to describe the collision history on SR 99 in
 6 terms of rate of occurrence, crash types, and severity. Collision rates are
 7 compared with average rates for similar highway facilities in Washington state to
 8 help determine whether SR 99 experiences a higher than typical rate of crashes.
 9 The corridor is also analyzed on a segment-by-segment basis to identify specific
 10 locations where collisions occur with higher frequency or greater severity.

11 Collision frequency, type, and severity were assessed for the length of SR 99
 12 between S. Spokane Street in the south and Valley Street in the north. The
 13 following key findings were identified for the SR 99 corridor:

- 14 • Collisions on SR 99 occur at higher frequencies than on average for urban,
 15 limited-access highways in the state. Collision rates are lower than
 16 average rates for urban principal arterials, however.

17 Individual segments of SR 99 were also assessed to determine where collisions
 18 occurred with higher than average frequencies or injury rates, as well as to
 19 identify predominant collision types.

- 20 • Both northbound and southbound directions of the S. Spokane Street to
 21 Stadiums segment experience low collision rates and low rates of injury
 22 collisions relative to the rest of the corridor.

- 1 • The southbound Downtown to Stadiums segment experiences high
2 collision rates and a high rate of injury collisions relative to the corridor
3 average.
- 4 • The northbound and southbound Battery Street Tunnel segments
5 experience much higher rates of collisions than the corridor on average.
6 Northbound, a substantial share of these crashes appear to be associated
7 with the Battery Street on-ramp.
- 8 • The northbound and southbound North of Battery Street Tunnel segments
9 in the South Lake Union area experience different crash types than
10 elsewhere on the corridor, including enter-at-angle collisions involving
11 side-street connections and pedestrian collisions, which are of concern due
12 to the vulnerability of pedestrians in collisions.

13 4.10.1 Methodology

14 WSDOT provided collision data for SR 99 between S. Spokane Street and Aloha
15 Street for the years 2005 to 2007. Data for these 3 years were analyzed to
16 determine important characteristics for collisions both on the mainline as well as
17 on connecting ramps within 250 feet of the mainline. Several analyses were used
18 to measure and assess collision characteristics:

- 19 • *Collision rates by segment.* To allow comparison of crash rates between
20 corridor segments as well as to average rates on other similar facilities,
21 collisions per MVMT were calculated for each corridor segment.
- 22 • *Collision types by segment.* The share of collisions for major crash types
23 (e.g., fixed-object collisions, rear-end collisions, etc.) relative to total
24 collisions are reported. Comparing the proportion of accident types by
25 segment can help identify possible contributing factors to collisions.
- 26 • *Collision severity by segment.* The share of injury collisions (injury collisions
27 per MVMT) relative to total collisions is reported.

28 4.10.2 Collision Rates by Segment

29 Collision frequency, expressed as the number of collisions per MVMT, is a
30 standardized measure useful in comparing collision rates between different
31 segments or even different highways. This section presents collision rates for the
32 major segments on SR 99, and for comparative purposes, average collision rates
33 for other similar highway facilities. Collision rates for other facilities should be
34 compared only in terms of general order of magnitude since variations in
35 methodology are common.

1 Segments Analyzed

2 Collision rates are calculated for five primary mainline segments on SR 99.
3 Generally, a segment was considered as beginning either 0.05 mile prior to an on-
4 ramp or following an off-ramp, and ending 0.05 mile after the next off-ramp or
5 before the next on-ramp. This definition typically results in uniform volumes and
6 lane configurations within a segment. Further, collisions occurring on the first
7 250 feet of a connecting on-ramp or off-ramp are also considered as having
8 occurred on the mainline.

9 Northbound

- 10 • S. Spokane Street to Stadiums: Prior to the S. Spokane Street on-ramp to
11 prior to the First Avenue S. on-ramp.
- 12 • Stadiums to Downtown: Prior to the First Avenue S. on-ramp to after the
13 Seneca Street off-ramp.
- 14 • Downtown to Battery Street Tunnel: After the Seneca Street off-ramp to
15 after the Western Avenue off-ramp.
- 16 • Battery Street Tunnel: After the Western Avenue off-ramp to prior to the
17 Denny Way on-ramp. Note that this segment includes the Battery Street
18 Tunnel as well as connecting mainline sections external to the tunnel.
- 19 • North of Battery Street Tunnel: Prior to the Denny Way on-ramp to after
20 Valley Street.

21 Southbound

- 22 • North of Battery Street Tunnel: Prior to Valley Street to after the Denny
23 Way off-ramp.
- 24 • Battery Street Tunnel: After the Denny Way off-ramp to prior to the
25 Elliott Avenue on-ramp (includes the Battery Street Tunnel). As with
26 northbound, this segment includes connecting mainline sections external
27 to the tunnel.
- 28 • Battery Street Tunnel to Downtown: Prior to the Elliott Avenue on-ramp
29 to prior to the Columbia Street on-ramp.
- 30 • Downtown to Stadiums: Prior to the Columbia Street on-ramp to after the
31 First Avenue S. off-ramp.
- 32 • Stadiums to S. Spokane Street: After the First Avenue S. off-ramp to after
33 the S. Spokane Street off-ramp.

34 As noted, the short distance between the Elliott/Western ramps and the Battery
35 Street ramps was not considered an independent segment, but rather was

1 grouped with the Battery Street Tunnel segment. The corridor north of the
2 Battery Street Tunnel was considered a single segment (North of Battery Street
3 Tunnel).

4 Collision Rates on SR 99

5 Collision rates are measured in terms of collisions per MVMT and include those
6 collisions occurring on the first 250 feet of any connecting ramps. Exhibits 4-40
7 and 4-41 summarize collision rates for the corridor.

8 In the northbound direction, SR 99 was found to have an overall collision rate of
9 1.83 collisions per MVMT. The collision rate for the S. Spokane Street to Stadiums
10 segment is very low—about 42 percent lower than the corridor average. The rate
11 of collisions on the Stadiums to Downtown segment is second highest of the five
12 northbound segments, with weaving movements and backups from the Seneca
13 Street and Western Avenue off-ramps likely contributing to higher collision rates
14 on the northbound Stadiums to Downtown segment. In addition, this segment
15 carries the highest volume of traffic on the corridor, which could also be a
16 contributing factor.

17 The Downtown to Battery Street Tunnel segment has a collision rate lower than
18 the corridor average, despite the fact that backups are regularly observed on this
19 segment. Collisions on the Western Avenue off-ramp—not included in the
20 mainline segment analysis—do occur with higher frequency than on other ramps,
21 however. The northbound Battery Street Tunnel segment has the highest overall
22 collision rate on the corridor. Frequent collisions here are associated with a
23 number of factors, including limited sight distance and tight curves within the
24 tunnel, lack of clear distance from the tunnel walls, and merging traffic entering
25 from the Battery Street on-ramp, which has limited sight distance and a very short
26 merge area. Collision rates on the North of Battery Street Tunnel segment in the
27 South Lake Union area are moderate in relation to other corridor segments.

28 Southbound, the overall mainline collision rate is higher than northbound:
29 2.03 collisions per MVMT, with segments showing a similar pattern of collision
30 occurrences relative to the corresponding northbound segments.

31 The southbound North of Battery Street Tunnel segment has a moderate collision
32 rate relative to other corridor segments. Though lower than the corresponding
33 northbound segment, the southbound Battery Street Tunnel segment also shows a
34 very high rate of collisions. Collision rates are quite low on the southbound
35 Battery Street Tunnel to Downtown segment, but jump substantially on the
36 adjacent Downtown to Stadiums segment. This segment includes a left-side
37 merging on-ramp from Columbia Street and a left-side off-ramp to First
38 Avenue S., and experiences recurrent congestion during the PM peak. The

1 southbound Stadiums to S. Spokane Street segment exhibits a relatively low
 2 collision rate, as expected given that the segment is largely a uniform
 3 configuration with few conflicts between traffic movements.

4 **Exhibit 4-40. Collision Rates for Northbound SR 99 Segments (2000–2003)¹**

Segment	Collisions per MVT
NB S. Spokane Street to Stadiums	1.07
NB Stadiums to Downtown	1.90
NB Downtown to Battery Street Tunnel	1.54
NB Battery Street Tunnel	5.46
NB North of Battery Street Tunnel	1.60
SR 99 Corridor Average	1.83

5 ¹ Includes collisions on ramps that occur within 250 feet of the mainline.

6 **Exhibit 4-41. Collision Rates for Southbound SR 99 Segments (2000–2003)¹**

Segment	Collisions per MVT
SB North of Battery Street Tunnel	1.51
SB Battery Street Tunnel	4.81
SB Battery Street Tunnel to Downtown	1.02
SB Downtown to Stadiums	4.54
SB Stadiums to S. Spokane Street	1.21
SR 99 Corridor Average	2.03

7 ¹ Includes collisions on ramps that occur within 250 feet of the mainline.

8 Comparing Collision Rates on SR 99 to Other Facilities

9 Exhibit 4-42 summarizes average systemwide collision rates reported for urban
 10 areas in Washington. While general comparisons may be made between collision
 11 rates on SR 99 and other facilities, factors such as inconsistencies in methodology,
 12 unique driver characteristics, and differences in local conditions may influence
 13 results. Further, SR 99 is a somewhat unique facility type and is not fully consist
 14 with the Interstate Freeway designation.

1 Exhibit 4-42. Average Systemwide Collision Rates Reported for Urban Areas

Segment	Collisions per MVMT
<u>SR 99</u>	
SR 99 Northbound Corridor Average	1.83
SR 99 Southbound Corridor Average	2.03
<u>Comparison of statewide collision rates</u>	
WSDOT Urban Interstate Freeways ¹	1.32–1.60
WSDOT Urban Principal Arterials (2000–2003) ¹	2.41–2.97

2 ¹ WSDOT Unpublished Collision Data for 2003, and 1996 WSDOT Highway Accident Report.
3

4 Collision rates on SR 99 are 14 to 54 percent higher than the average systemwide
5 collision rates historically reported for urban, limited-access freeways in
6 Washington. Note that the most recent available data showed a statewide rate of
7 1.32 collisions per MVMT in 2003, while rates dating back to 1996 have been as
8 high as 1.60 collisions per MVMT.

9 Collision rates for principal arterials are provided for added context as well.
10 SR 99 collision rates are 16 to 38 percent lower than systemwide averages for
11 urban principal arterials in Washington.

12 **Collision Type by Segment**

13 To help identify possible factors associated with collisions, the proportion of
14 collisions by type was reviewed for the major corridor segments (Exhibits 4-43
15 and 4-44). Collision types include:

- 16 • Fixed-object: Collisions with roadside barriers or objects (walls, guardrail,
17 other roadside appurtenance).
- 18 • Read-end: Collisions where one or more vehicles strike slower-moving or
19 stopped vehicles from behind.
- 20 • Sideswipe: Side-to-side collisions between two vehicles traveling in the
21 same direction, often involving a lane change or straying from the travel
22 lane.
- 23 • Enter-at-angle: Collisions with vehicles entering the roadway from side-
24 street connections.
- 25 • Pedestrian: Collisions between vehicles and pedestrians or bicycles.
- 26 • Other/Unknown: All other collision types, including wrong direction of
27 travel, overturned vehicle, and other unknown or unclassified collision
28 types.

1 Exhibit 4-43 summarizes the share of collisions by crash type for northbound
 2 SR 99. Fixed-object (34 percent), rear-end (37 percent), and sideswipe (17 percent)
 3 collisions predominate on northbound SR 99. Fixed-object collisions are most
 4 prevalent northbound on the following segments:

- 5 • 49 percent of collisions are fixed-object on the northbound S. Spokane
 6 Street to Stadiums segment.
- 7 • 33 percent of collisions are fixed-object on the northbound Stadiums to
 8 Downtown segment.
- 9 • 34 percent of collisions are fixed-object on the northbound Battery Street
 10 Tunnel segment.

11 **Exhibit 4-43. Mainline Collision Types for Northbound SR 99 Segments**

Segment	Collision Types					
	Fixed-Object	Rear-End	Sideswipe	Enter-at-Angle	Pedestrian	Unknown/Other ¹
NB S. Spokane Street to Stadiums	49%	31%	11%	0%	0%	9%
NB Stadiums to Downtown	33%	32%	26%	0%	0%	9%
NB Downtown to Battery Street Tunnel	23%	57%	20%	0%	0%	0%
NB Battery Street Tunnel	34%	47%	13%	0%	0%	6%
NB North of Battery Street Tunnel	10%	18%	21%	33%	8%	10%
SR 99 Corridor Average	34%	37%	17%	4%	1%	7%

12 ¹ Roll over, wrong direction of travel, or unknown/unclassified

13 Rear-end collisions account for especially high shares of collisions on the
 14 northbound Downtown to Battery Street Tunnel segment (57 percent) and
 15 adjacent Battery Street Tunnel segment (47 percent). Queuing from the Western
 16 Avenue off-ramp is likely a primary factor associated with the high share of rear-
 17 end collisions on the first segment, while limited sight distances and merging
 18 traffic from the Battery Street on-ramp contribute to high shares of rear-end
 19 collisions on the Battery Street Tunnel segment.

20 Sideswipe collisions tend to occur more frequently on segments where frequent
 21 lane changing occurs to access connections to/from SR 99 (i.e., northbound

1 Stadiums to Downtown, Downtown to Battery Street Tunnel, and North of
2 Battery Street Tunnel segments).

3 The northbound North of Battery Street Tunnel segment is unique in that enter-
4 at-angle collisions occur frequently (33 percent) as a result of the existing side-
5 street connections. This segment also experiences collisions involving pedestrians
6 (8 percent), which are a particular concern due to the typical severity of such
7 collisions in terms of injury to the pedestrian.

8 Exhibit 4-44 summarizes the share of collisions by crash type for southbound
9 SR 99. As found in the northbound direction, the southbound North of Battery
10 Street Tunnel segment also experiences enter-at-angle collisions, though at a
11 lower rate (9 percent). Pedestrian collisions (9 percent) are again a concern on this
12 segment.

13 **Exhibit 4-44. Mainline Collision Types for Southbound SR 99 Segments**

Segment	Collision Types					
	Fixed-Object	Rear-End	Sideswipe	Enter-at-Angle	Pedestrian	Unknown/Other ¹
SB North of Battery Street Tunnel	15%	35%	24%	9%	9%	9%
SB Battery Street Tunnel	52%	22%	8%	8%	1%	9%
SB Battery Street Tunnel to Downtown	11%	57%	14%	0%	0%	17%
SB Downtown to Stadiums	33%	31%	24%	0%	0%	12%
SB Stadiums to S. Spokane Street	29%	44%	14%	0%	0%	13%
SR 99 Corridor Average	33%	35%	16%	3%	1%	12%

14 ¹ Roll over, wrong direction of travel, or unknown/unclassified

15
16 The share of fixed-object collisions is very high (52 percent) for the southbound
17 Battery Street Tunnel segment, where a combination of excessive speed and
18 limited lateral clearance in the Battery Street Tunnel are likely factors associated
19 with this type of collision. Note that enter-at-angle collisions here are associated
20 with the Battery Street off-ramp and street connections to that ramp.

21 Sideswipe collisions again tend to account for a greater share of collisions in
22 locations where ramp locations and configurations lead to more lane changing
23 activity. This is true on the southbound North of Battery Street Tunnel and
24 Downtown to Stadiums segments.

1 Rear-end collisions predominate on the southbound Battery Street Tunnel to
 2 Downtown and Stadiums to S. Spokane Street segments, though as discussed in
 3 the following section, the frequency of collisions in general is low on this
 4 segment.

5 **Collision Severity by Segment**

6 Exhibits 4-45 and 4-46 summarize collision severity for SR 99 corridor segments.
 7 Collisions are classified as either property-damage-only collisions or injury
 8 collisions. The latter category includes crashes that were identified in collision
 9 reports as possible injury, evident injury, debilitating injury, or fatal collisions.

10 **Exhibit 4-45. Collision Severity for Northbound SR 99 Segments**

Segment	Property Damage Only	Injury
NB S. Spokane Street to Stadiums	63%	37%
NB Stadiums to Downtown	63%	37%
NB Downtown to Battery Street Tunnel	59%	41%
NB Battery Street Tunnel	65%	35%
NB North of Battery Street Tunnel	59%	41%
SR 99 Corridor Average	63%	37%

11

12 **Exhibit 4-46. Collision Severity for Southbound SR 99 Segments**

Segment	Property Damage Only	Injury
SB North of Battery Street Tunnel	59%	41%
SB Battery Street Tunnel	67%	33%
SB Battery Street Tunnel to Downtown	49%	51%
SB Downtown to Stadiums	58%	42%
SB Stadiums to S. Spokane Street	51%	49%
SR 99 Corridor Average	58%	42%

13

14 Northbound, injury collisions account for on average 37 percent of all collisions.
 15 Variation by segment is minor, with all segments showing injury rates of between
 16 35 and 41 percent. The northbound Downtown to Battery Street Tunnel and
 17 North of Battery Street Tunnel segments shows the highest percentage of injury
 18 collisions. While a lower share of collisions on the Battery Street Tunnel segment

1 involve injuries, the number of injury collisions is still relatively high due to the
2 overall higher frequency of collisions here.

3 Southbound shows a higher variation in severity by segment. About half of
4 collisions on the southbound Battery Street Tunnel to Downtown and Stadiums to
5 S. Spokane Street segments involve injuries, though these segments have lower
6 collision frequencies overall.

7 Conclusions

8 The frequency of collisions on the SR 99 corridor is higher than average rates for
9 urban, limited-access highways in the state. Collisions on the SR 99 corridor
10 occur at a corridorwide rate of 1.83 to 2.03 collisions per MVMT, compared to a
11 historical average of 1.32 to 1.60 collisions per MVMT for all urban, limited-access
12 corridors in Washington.

13 Some segments of SR 99 exhibit elevated collision rates relative to the corridor
14 average. The northbound and southbound Battery Street Tunnel segments
15 (Western/Elliott Avenue ramps to Denny Way ramps) show much higher
16 collision rates than most other segments on the corridor. Northbound, a
17 substantial share of these crashes appears to be associated with the Battery Street
18 on-ramp. Review of collision locations also indicates that collision frequencies are
19 higher in the curved section of the tunnel, where excessive speed, sight distance
20 limitations, and limited roadside clearance are all possible contributing factors.

21 The southbound Downtown to Stadiums segment (southbound SR 99 between the
22 Columbia Street on-ramp and First Avenue S. off-ramp) also experiences an
23 elevated crash rate and moderately high rate of injury collisions relative to the rest
24 of the corridor. A combination of factors likely contributes to these elevated crash
25 rates, including narrow lanes, little roadside clearance, a left-side merge from
26 Columbia Street, a left-side diverge to First Avenue S., heavy weaving movements
27 associated with left-side on- and off-ramp traffic, and high congestion levels.

28 The northbound and southbound segments north of the Battery Street Tunnel
29 (Denny Way ramps to north of Valley Street) in the South Lake Union area also
30 exhibit moderate collision rates, but unique crash types. The numerous right-
31 angle street connections to SR 99 are a factor in a large share of collisions on this
32 segment, with high rates of enter-at-angle, sideswipe, and rear-end collisions.
33 Pedestrian collisions are a particular concern in this area, as SR 99 is at-grade and
34 pedestrians crossing the roadway (illegally) have been involved in a number of
35 collisions. These collisions tend to most often involve fatalities or serious injury.

1 4.10.3 Corridor Design Aspects

2 SR 99 is a multi-lane, divided highway that travels through downtown Seattle
3 within the study area. SR 99 is not a fully limited-access facility and does not
4 meet access and other criteria normally associated with a freeway facility. As
5 such, it most closely matches FHWA's "Principal Arterial – Other Freeways and
6 Expressways" category. The City of Seattle classifies SR 99 simply as a "Principal
7 Arterial."

8 Access to and from SR 99 is provided by ramp connections between S. Spokane
9 Street and the Battery Street Tunnel and by right-angle street connections north of
10 the Battery Street Tunnel. SR 99 was constructed in the 1950s and was designed
11 to meet geometric standards that are less stringent than those typical for new
12 highways today. Lane widths, shoulder widths, acceleration and deceleration
13 lanes, and other geometric features on SR 99 generally conform to a lesser
14 standard than those found on newer highway facilities.

15 4.11 Event Traffic

16 South Portal Area

17 During events at Safeco Field or Qwest Field, traffic levels in the general vicinity
18 intensify within a relatively short amount of time, travel patterns change as
19 patrons search for parking, and pedestrian activity increases. As a result, local
20 traffic conditions are typically much more congested prior to and following
21 events compared to typical, non-event conditions (discussed previously). As an
22 example, for a typical Seahawks game, estimates indicate that between 15,000 and
23 20,000 additional vehicles, beyond background traffic levels, enter and exit the
24 stadium area.

25 Regional access to northbound SR 99 and from southbound SR 99 is currently
26 provided for events via the on- and off-ramps at First Avenue S. SR 99
27 connections to/from the south are not provided in the stadium area. Nearby
28 access points to/from downtown along SR 99 include a northbound off-ramp to
29 Seneca Street and a southbound on-ramp from Columbia Street. No direct SR 99
30 access to or from the north is provided in the downtown area. The West Seattle
31 travel market for events in the south end is served by SR 99 with an eastbound-to-
32 northbound loop ramp and a reverse southbound-to-westbound ramp.

33 Additional regional access to/from the stadium area is provided by the following:

- 34 • To/from I-5 via SR 519 from Fourth Avenue S. (elevated intersection)
- 35 • To/from I-5 via Fourth Avenue S. and Industrial Way
- 36 • To/from I-5 via SR 99 and SR 599 to the south

- 1 • To/from S. Spokane Street at Sixth Avenue S.
- 2 • To/from I-90 via Fourth Avenue S. at SR 519 or from S. Spokane Street
- 3 Explicit detour routing and comprehensive traffic control measures are typically
- 4 in place on First Avenue S. and critical east-west arterials (e.g., S. Royal
- 5 Brougham Way and S. Atlantic Street) for large events at Safeco Field and Qwest
- 6 Field such as Seahawks and Mariners Games and Sounders Matches. These
- 7 measures commonly include police-based traffic management commissioned by
- 8 the City of Seattle. Mode shift to alternative means of travel, particularly public
- 9 transit (bus, light rail, commuter rail, walking, etc.), often occurs for events at
- 10 both venues. As services increase and/or are enhanced for transit modes, event-
- 11 related ridership to/from the stadium area will likely increase over time.

12 North Portal Area

13 Seattle Center is the major event facility in the north portal area of the project.

14 This facility is home to several annual events, including Bumbershoot, Northwest

15 Folklife Festival, and Seattle Storm Women’s National Basketball Association

16 (WNBA) games. Other large-scale events related to holidays and children’s

17 programs also occur throughout the year.

18 A primary route to Seattle Center is from I-5 via the Mercer Street exit to Valley

19 Street and Broad Street. From Seattle Center to I-5, Mercer Street provides a

20 connection to northbound and southbound I-5. Additional routes to and from

21 Seattle Center include the following:

- 22 • Ballard: via Denny Way and Western Avenue W.
- 23 • To SR 99 southbound: via Broad Street and Thomas Street to Aurora
- 24 Avenue or via Broad Street and Elliott Avenue.
- 25 • To SR 99 northbound: via Second Avenue to Battery Street or via Mercer
- 26 Street, Dexter Avenue N., and Thomas Street.
- 27 • To I-5 southbound: via Second Avenue to Spring Street or via Denny Way
- 28 to Yale Avenue.
- 29 • To I-5 northbound: via Denny Way, Boren Avenue, and Olive Way.

30 For larger events at Seattle Center, traffic control measures and minor detours are

31 occasionally used to manage access to parking and general circulation. However,

32 due to the smaller scale of events and the capacity of the Seattle Center facility, such

33 measures are not in place as consistently nor are they required as frequently

34 compared to the larger sporting venues in the south (Safeco Field and Qwest Field).

35 Transit service for events at Seattle Center are not well-served compared to the

- 1 south end stadium area. However, local bus and monorail service is provided
- 2 to/from the downtown core (and to/from some neighborhoods on the periphery).

This Page Intentionally Left Blank

Chapter 5 OPERATIONAL EFFECTS, MITIGATION, AND BENEFITS

This chapter describes the changes in travel patterns and traffic volumes for the 2015 Baseline, Viaduct Closed (No Build Alternative), and Project scenarios and the 2030 Project scenario.

5.1 Regional Context and Travel Patterns

The discussion of the regional context and travel patterns illustrates how travel patterns might change in the future; it includes AM and PM peak period and daily estimates of various travel parameters (e.g., VMT) for routes that represent major movements accommodated by the SR 99 corridor.

5.1.1 Vehicle Miles of Travel

VMT for this study is defined as the total number of miles traveled in either the four-county Puget Sound region or the Seattle Center City study area for a given time period. The discussions below describe estimated VMT for AM and PM peak periods and daily totals for the 2015 Baseline, Viaduct Closed (No Build Alternative), and Project (Bored Tunnel Alternative) scenarios and the 2030 Project (Bored Tunnel Alternative) scenario. These estimates were derived by the project's traffic demand model. Exhibit 5-1 provides a summary table of VMT.

Key Findings

- AM, PM, and daily VMT are about equal for all 2015 scenarios for the four-county Puget Sound region; this is because the impacts of the various SR 99 scenarios would have little effect on overall multi-county trip making. However, if we look at just the Seattle Center City area, changes to VMT are more notable because changes to SR 99 would cause greater impacts at this subarea level.
- The 2015 Viaduct Closed (No Build Alternative) shows substantially lower VMT for the Center City area than the other 2015 scenarios (Baseline, Project, and Program), regardless of time period. This is likely due to a disincentive of trip making either to or through the Center City area caused by increased traffic and congestion on city streets. Under the 2015 Viaduct Closed (No Build Alternative), roughly 100,000 daily trips on SR 99 would need to be accommodated either by local street capacity, I-5, transit, or bike and walk modes.

- The 2015 Project scenario shows a very slight decrease in daily VMT compared with the 2015 Baseline scenario. The slight decrease is likely due to the removal of access between SR 99 and the Magnolia/Interbay/Ballard areas presumed in the Bored Tunnel alternative.

5 **Exhibit 5-1. Vehicle Miles of Travel**

Performance Measure	Existing (2005)	Year 2015			2030 Project
		Baseline	Viaduct Closed (No Build Alternative)	Project	
Seattle Center City					
AM	385,400	422,100	381,800	416,000	432,300
PM	472,400	523,400	476,000	516,000	541,300
Daily	2,118,200	2,371,600	2,175,000	2,342,900	2,463,600
Four-County Region					
AM	13,830,000	15,803,200	15,739,200	15,799,100	17,665,800
PM	16,116,800	18,562,800	18,508,900	18,558,000	20,831,900
Daily	73,622,500	84,769,700	84,501,000	84,754,100	94,955,300

6

7 For the 2015 Viaduct Closed (No Build Alternative), daily and AM and PM peak
 8 period VMT for the four-county region are about the same as those for the 2015
 9 Baseline and 2015 Project scenarios. However, in the Center City area, AM Peak
 10 period VMT for the Viaduct Closed (No Build Alternative) is over 10 percent
 11 lower than for the 2015 Baseline scenario and over 9 percent lower than for the
 12 2015 Project scenario. In the AM peak period, the Viaduct Closed (No Build
 13 Alternative) VMT is almost 11 percent lower than for the Baseline and 9 percent
 14 lower than for the Project. Lower VMT in the Center City area under the 2015
 15 Viaduct Closed (No Build Alternative) is probably the result of increased
 16 congestion and delay due to the closure of the viaduct and redistribution of trips
 17 from this facility to congested surface streets, which would tend to discourage
 18 travel in this area.

19 For the 2015 Baseline scenario, daily VMT for the four-county Puget Sound region
 20 increase by about 15 percent over existing conditions (2005) levels, resulting from
 21 the forecasted growth in regional population and employment within the four-
 22 county region. Comparable increases in VMT are shown for the AM and PM
 23 peak periods. The 2015 Project scenario shows a very slight decrease in daily
 24 miles traveled in comparison with the 2015 Baseline scenario, both regionwide
 25 and for the Center City area. The slight decrease is likely due to the removal of

1 access to the Magnolia/Interbay/Ballard areas in the Bored Tunnel Alternative.
2 The 2015 Baseline scenario assumes that the ramps at Elliott and Western
3 Avenues provide access to trips to and from northwest Seattle.

4 Daily VMT for the four-county region increases by 12 percent over the 2015
5 Baseline and Project scenarios. The 2030 VMT increase in the Center City area is
6 expected to be less, however, at approximately 5 percent over 2015 Project
7 conditions. For the 2030 Project, in the AM peak period, the 2030 Project VMT is
8 expected to grow by about 4 percent over 2015 Project levels and by more than
9 2 percent over 2015 Baseline levels for the Center City area. For the PM peak
10 period, the 2030 Project VMT is expected to grow by more than 3 percent over
11 2015 Baseline levels and by 5 percent over 2015 Project levels.

12 5.1.2 Vehicle Hours of Travel

13 VHT is defined as the calculated total number of hours traveled in either the four-
14 county Puget Sound region or the Seattle Center City study area for a given time
15 period. The VHT estimates discussed below were derived by the project's travel
16 demand model. The evaluation describes AM and PM peak period and daily
17 VHT totals for the 2015 Baseline, Viaduct Closed (No Build Alternative), and
18 Project scenarios and the 2030 Project scenario. Exhibit 5-2 provides a summary
19 table of VHT.

20 Key Findings

- 21 • Under the 2015 Baseline scenario, daily VHT for the four-county Puget
22 Sound region is projected to grow by more than 25 percent over existing
23 conditions (2005) levels. Comparable levels of growth in daily VHT are
24 found in the Center City area, as well as in the AM and PM peak periods
25 for both the four-county and Center City areas.
- 26 • Increased congestion levels brought about by the closure of the viaduct in
27 the Viaduct Closed (No Build Alternative) are likely causing the
28 measurable increase in VHT over the 2015 Baseline and Project levels.
- 29 • By 2030, the greatest percentage growth in VHT is expected to occur
30 outside of the City of Seattle due to higher growth rates in population and
31 employment outside of the city.

32 Under the 2015 Baseline, daily VHT for the four-county region increases by about
33 27 percent over comparable existing conditions levels. The 2015 Baseline AM
34 peak period VHT is also forecasted to grow by more than 36 percent over existing
35 conditions levels, and VHT for the PM peak period 2015 Baseline scenario is
36 forecasted to increase similarly, by almost 35 percent over the comparable
37 existing conditions levels. The daily and AM and PM peak period 2015 Baseline

1 scenario shows VHT for the four-county region about equal to those forecasted
 2 for the 2015 Project scenario.

3 **Exhibit 5-2. Vehicle Hours of Travel**

Performance Measure	Existing (2005)	Year 2015			2030 Project
		Baseline	Viaduct Closed (No Build Alternative)	Project	
Seattle Center City					
AM	13,200	16,200	17,500	16,500	18,000
PM	17,600	22,900	25,500	23,600	29,600
Daily	67,500	83,000	87,500	84,300	96,600
Four-County Region					
AM	452,100	615,800	614,000	616,400	945,600
PM	517,800	697,700	700,100	698,700	1,037,500
Daily	2,021,800	2,568,800	2,569,900	2,571,000	3,532,500

4 Note: The VHT estimates do not include centroid connectors in the calculations.
 5

6 For the 2015 Viaduct Closed (No Build Alternative), daily and AM and PM peak
 7 period VHT for the four-county region are forecasted to be about the same as
 8 those for the 2015 Baseline and 2015 Project scenarios.

9 In the Center City area, during the AM peak period, the 2015 Viaduct Closed (No
 10 Build Alternative) is 8 percent higher than for the 2015 Baseline scenario and
 11 6 percent higher than for the 2015 Project scenario. During the PM peak period,
 12 the Viaduct Closed (No Build Alternative) shows over 11 percent higher VHT
 13 than the 2015 Baseline scenario and 8 percent higher than the 2015 Project
 14 scenario. Daily VHT is slightly higher for 2015 Viaduct Closed (No Build
 15 Alternative) than for the 2015 Baseline (4 percent) and 2015 Project (5 percent)
 16 scenarios. Increased congestion levels brought about by the closure of the
 17 Alaskan Way Viaduct and no replacement in capacity (assumed under the
 18 Viaduct Closed [No Build Alternative]) are likely causing the measurable increase
 19 in VHT over 2015 Baseline and Project scenarios.

20 For the 2030 Project scenario, daily VHT for the four-county region is expected to
 21 grow from the 2015 Project level by approximately 37 percent. AM peak period
 22 VHT is forecasted to increase by 53 percent, and PM peak period VHT by
 23 48 percent. In the Center City area, however, VMT is expected to grow by only
 24 9 percent in the AM peak period, 25 percent in the PM peak period, and
 25 15 percent on a daily basis between the 2015 and 2030 Project scenarios. The
 26 reason for the higher percentage growth in VHT for the four-county region over

1 the Center City area is likely the higher overall growth in population and
 2 employment forecasted to occur outside of the city of Seattle.

3 **5.1.3 Vehicle Hours of Delay**

4 VHD is defined as the calculated total number of hours during which normal
 5 traffic flows exceed roadway capacity in either the four-county Puget Sound
 6 region or the Seattle Center City study area for a given time period. This measure
 7 is often used as an indicator of overall traffic congestion. The VHD estimates
 8 were derived by the project’s travel demand model. The evaluation describes AM
 9 and PM peak periods and daily totals for the 2015 Baseline, Viaduct Closed (No
 10 Build Alternative), and Project scenarios and the 2030 Project scenario.
 11 Exhibit 5-3 provides a summary table of VHD.

12 **Key Findings**

- 13 • Looking at activity in the Center City area, increased congestion levels
 14 brought about by the closure of the viaduct are likely causing the
 15 measurable increase in VHD over 2015 Baseline and Project levels.
- 16 • By 2030, a higher percentage growth in VHD is projected to occur outside
 17 the city of Seattle, reflecting the fact that a higher number of new trips
 18 to/from downtown are expected to be accommodated by transit in the
 19 future.

20 **Exhibit 5–3. Vehicle Hours of Delay**

Performance Measure	Existing (2005)	Year 2015				2030 Project
		Baseline	Viaduct Closed (No Build Alternative)	Project		
Seattle Center City						
AM	3,500	5,300	7,100	5,700	6,800	
PM	5,400	9,200	12,400	10,000	15,100	
Daily	14,500	22,900	30,000	24,500	33,200	
Four-County Region						
AM	137,600	253,500	252,700	254,200	531,500	
PM	149,900	271,800	274,800	272,800	548,100	
Daily	384,800	678,100	682,600	680,200	1,370,400	

21
 22 In 2015, during the AM peak period, the Baseline scenario VHD for the four-
 23 county region increases by about 84 percent over the comparable existing

1 conditions (2005) VHD. The Baseline PM peak period VHD increases by
2 81 percent over the existing conditions VHD, and daily VHD for the Baseline
3 scenario increases by about 76 percent over the comparable existing conditions
4 VHD. The 2015 Baseline scenario shows daily and AM and PM peak period VHD
5 about equal to those forecasted for the 2015 Project, both regionwide and for the
6 Center City area.

7 The 2015 Viaduct Closed (No Build Alternative) shows about the same levels of
8 VHD as those for the 2015 Baseline and Project scenarios for the daily and AM
9 and PM peak periods in the four-county region. Looking at the Center City area,
10 however, the daily VHD for the Viaduct Closed (No Build Alternative) is
11 substantially higher than for the Baseline (31 percent) and Project (22 percent)
12 scenarios. In the AM peak period, the Viaduct Closed (No Build Alternative) also
13 shows similar VHD increases over those for the Baseline (34 percent) and Project
14 (25 percent) scenarios, while in the PM peak period, the Viaduct Closed (No Build
15 Alternative) continues to show higher VHD than the Baseline (35 percent) and
16 Project (24 percent) scenarios.

17 For the 2030 Project scenario, daily VHD levels for the four-county region are
18 expected to grow from 2015 Project levels by approximately 102 percent. AM
19 peak period VHD is forecasted to increase by 110 percent, and PM peak period
20 VHD by 102 percent. However, VHD growth within the Center City area
21 between the 2015 and 2030 Project scenarios is expected to be lower, at 19 percent,
22 51 percent and 36 percent for the AM, PM and daily periods, respectively. The
23 lower rate of increase expected within the Center City area is likely due to the fact
24 that with the proposed enhancements to transit serving downtown, much of the
25 growth in trips is expected to be accommodated by transit as opposed to
26 additional vehicle trips.

27 5.1.4 Alaskan Way Viaduct (SR 99) Users

28 The following sections present data that describe users of SR 99 within the study
29 area for the 2015 Baseline and Project scenarios.

30 Key Findings

- 31 • Traffic patterns of SR 99 users for the 2015 Baseline scenario are expected
32 to be similar to those described for existing conditions, except that less
33 traffic is expected to use the midtown ramps due to a shift to the stadium
34 ramps. The stadium ramps are also expected to attract some traffic to
35 SR 99 that would have otherwise used First Avenue S. to reach
36 destinations in the SODO area.

- 1 • The Bored Tunnel Alternative would serve a higher percentage of through
2 traffic to/from SR 99/Aurora Avenue north of the project area than the
3 current facility does. Of the 81,100 trips projected to use the bored tunnel
4 in the 2015 Baseline scenario, 70 percent are expected to come from Aurora
5 Avenue north of Aloha Street, and 30 percent from the South Lake Union
6 area. This compares to current through trips on SR 99 of roughly
7 46 percent from Aurora Avenue north of Aloha Street and 17 percent from
8 South Lake Union. (Note that the Elliott/Western ramps provide the other
9 38 percent of the existing through traffic.)
- 10 • Some traffic that would have otherwise used the Elliott/Western ramps to
11 access SR 99 is expected to use Mercer Street to access SR 99 at the South
12 Lake Union area ramps instead. This contributes to the relatively
13 high percentage of bored tunnel traffic (30 percent) accessing SR 99 from
14 the South Lake Union area.
- 15 • The new stadium area ramps to/from the south are expected to serve both
16 traffic destined for downtown (i.e., the traffic that currently uses the
17 midtown ramps) as well as a large share of the traffic destined for the
18 Interbay area, Magnolia, and northwest Seattle (i.e., traffic that currently
19 uses the Elliott/Western ramps).

20 SR 99 Daily Traffic Patterns – 2015 Baseline

21 Traffic patterns of SR 99 users for the 2015 Baseline scenario are expected to be
22 similar to those described for Existing Conditions, except that less traffic is
23 expected to use the midtown ramps due to a shift to the stadium ramps. The
24 stadium ramps are also expected to attract some traffic to SR 99 that would have
25 otherwise used First Avenue S. to reach destinations in the SODO area.

26 SR 99 Daily Traffic Patterns – 2015 Project

27 Exhibit 5-4 shows the projected daily traffic patterns on SR 99 within the study
28 area in the 2015 Project scenario. Blue lines indicate trips that use the viaduct
29 (SR 99 between the stadium area and Battery Street Tunnel), while red lines show
30 trips that use SR 99 (Aurora Avenue) but enter or exit north of the viaduct.
31 Arrows indicate locations where traffic enters or exits the corridor, with each
32 arrow representing a ramp movement. Because access in the South Lake Union
33 area is provided by many closely spaced cross-streets, these movements are
34 shown grouped.

35 At the north end of the study area (on Aurora Avenue), about 40 percent of trips
36 using SR 99 are expected to enter and exit the corridor north of the Battery Street
37 Tunnel. Of the 94,900 daily vehicle trips on Aurora Avenue, 38,100 trips would
38 enter and exit in the South Lake Union area.

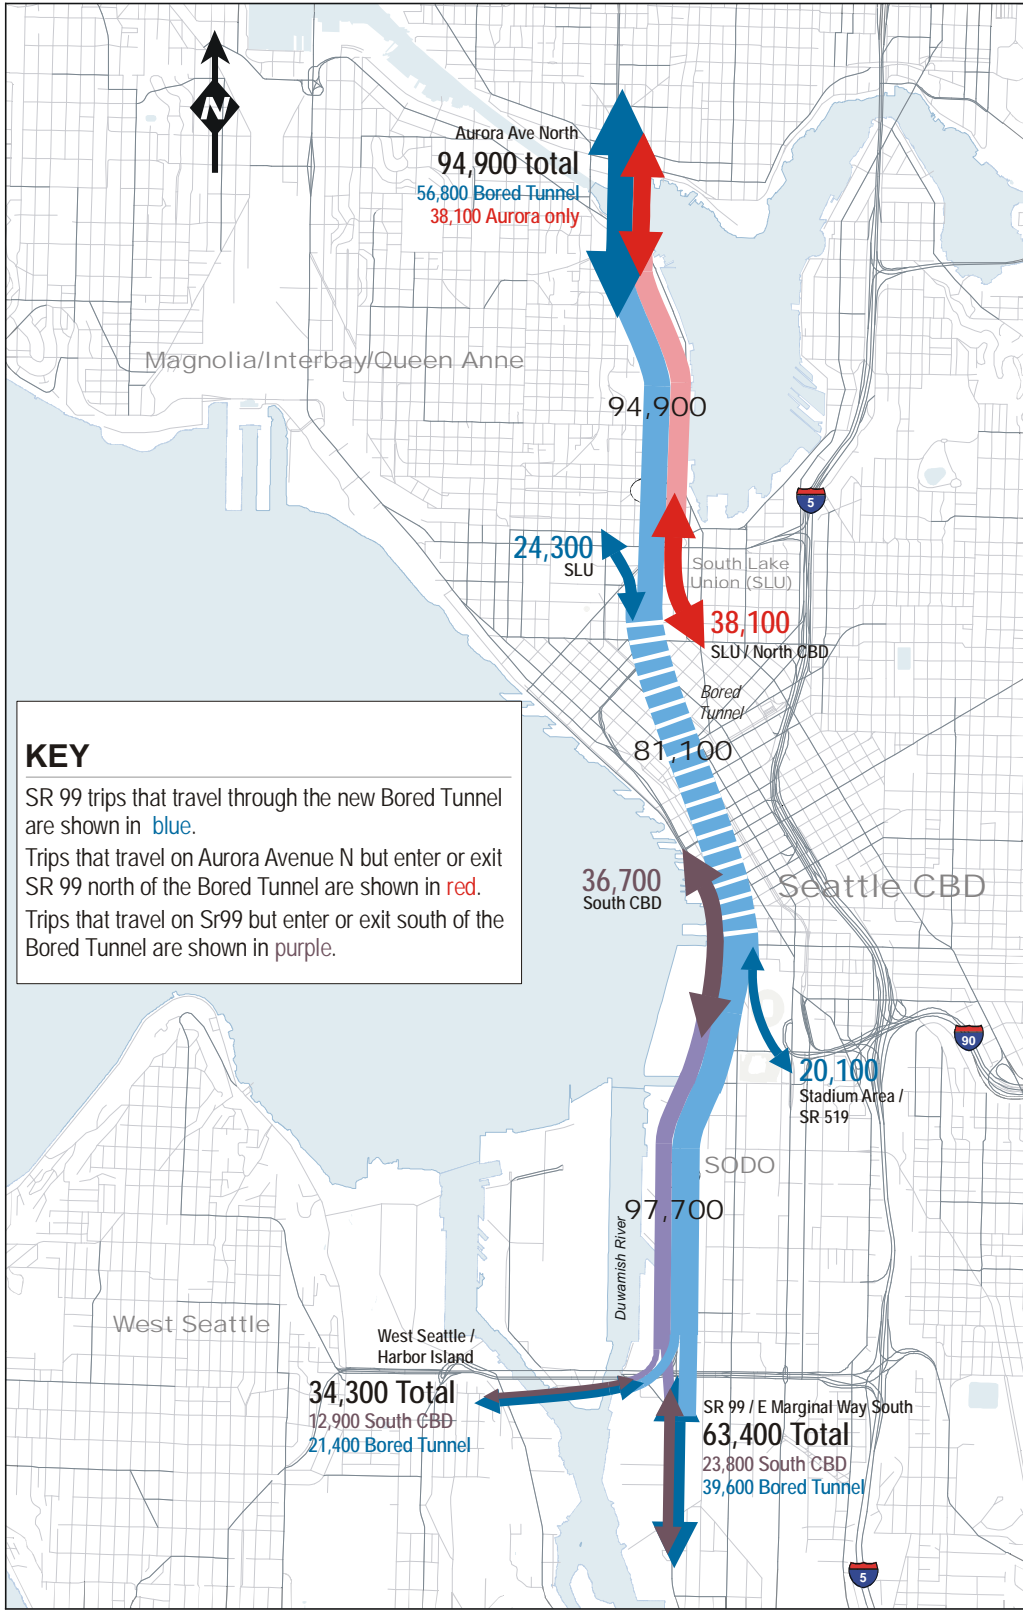

Exhibit 5-4
Daily SR 99 Traffic Patterns - 2015 Project

1 Some 81,100 vehicles are projected to use the bored tunnel on a typical weekday.
2 Seventy percent of the bored tunnel traffic consists of the remainder (56,800 trips)
3 of the Aurora Avenue trips; the 24,300 additional trips (or 30 percent of the bored
4 tunnel traffic) enter and exit the corridor in the South Lake Union area.

5 At the south end of the downtown area, 36,700 vehicles are anticipated to travel
6 between SR 99 south of the project area and the ramps at S. King Street. An
7 additional 20,100 vehicles would exit SR 99 southbound or enter it northbound
8 using the stadium area ramps.

9 At S. Spokane Street, 34,300 vehicles are projected to exit/enter the corridor
10 to/from the west via either the West Seattle high bridge or the low bridge to
11 Harbor Island. About two-thirds of those vehicles (21,400) are estimated to be
12 vehicles emerging from or destined for the bored tunnel, while the remainder
13 would be vehicles that would enter or exit south of the CBD. Approximately
14 63,400 trips would exit/enter the corridor to/from SR 99 south of S. Spokane
15 Street. Again, almost two-thirds of these vehicles would be coming from or going
16 to the bored tunnel, while the remainder would be vehicles entering or exiting
17 south of the CBD.

18 5.1.5 Screenline Vehicle Volumes

19 AM and PM peak period and daily traffic volumes were assessed to gauge the
20 general impacts to parallel streets and highways. Traffic volume forecasts from
21 the project were measured at four screenline locations:

- 22 • A south screenline north of S. Spokane Street (referred to as the Spokane
23 screenline), representing traffic entering and exiting the study area from
24 and to the south.
- 25 • A south screenline south of S. King Street, representing traffic entering
26 and exiting the study area at the south end of downtown.
- 27 • A central screenline north of Seneca Street, capturing north/south traffic
28 flows in the center of the study area.
- 29 • A north screenline located north of Thomas Street, representing traffic
30 entering and exiting the study area to the north.

31 Screenline volume results are presented in Exhibit 5-5. Additionally, daily
32 volumes along key facilities (Alaskan Way, SR 99, and I-5) and arterial screenline
33 volumes at locations generally similar to the above screenlines were compared
34 across the scenarios and are shown graphically in Exhibits 5-6 and 5-7. Daily
35 traffic volumes at two additional screenlines, east and west of Aurora Avenue, in
36 north Seattle were also measured, representing the traffic traveling to and from
37 the SR 99 corridor between the Ship Canal and Northgate Way. These results are
38 shown graphically in Exhibit 5-8.

1 Key Findings

- 2 • The Alaskan Way surface street is projected to experience 24 to 37 percent
3 heavier traffic than under Baseline conditions, but still 24 to 39 percent less
4 than under the Viaduct Closed (No Build Alternative).
- 5 • For all screenlines assessed, both the 2015 Project and Baseline scenarios
6 carry about the same amount of traffic (they show a 1 percent or less
7 difference), which shows that the bored tunnel would accommodate a
8 similar number of trips as under the Baseline condition even though
9 access points in the corridor would have changed.
- 10 • The 2015 Project scenario shifts additional trips to the Alaskan Way
11 surface street, which is projected to experience 24 to 37 percent heavier
12 traffic than under Baseline conditions (but still 24 to 39 percent less than
13 under the Viaduct Closed [No Build Alternative]). This shift is due to the
14 changes to the Ballard/Interbay access to SR 99.
- 15 • For the Spokane and south screenlines, the Viaduct Closed (No Build
16 Alternative) would have lower vehicle volumes than the 2015 Baseline and
17 2015 Project scenarios during congested peak periods. This is likely the
18 result of an overall redistribution of trips and a reduction in demand to
19 and through downtown Seattle due to reduced capacity through the
20 central waterfront.
- 21 • As reflected in the central screenline, in the Viaduct Closed (No Build
22 Alternative), dramatic increases are expected in Alaskan Way traffic and,
23 to a lesser extent, other downtown north-south arterials due to removal of
24 the viaduct and a shift of many of those viaduct trips to parallel arterials.
- 25 • New east-west connections across Aurora Avenue contained in the Project
26 scenario provide greater mobility in the South Lake Union area and
27 promote better utilization of the street grid.
- 28 • East-west traffic volumes on arterials both east and west of Aurora
29 Avenue north of the Ship Canal are expected to be similar among the 2015
30 Baseline and Project scenarios, indicating that diversion from the 15th
31 Avenue N.W./Elliott Avenue N. corridor to SR 99 or I-5 is not expected to
32 occur.
- 33

1 Exhibit 5-5. Model-Estimated Vehicle Volumes at Screenlines

	2005 Existing	2015 Baseline	Viaduct Closed (No Build Alternative)	2015 Project	2030 Project
Spokane Screenline (North of S. Spokane Street)					
AM	31,060	33,310	30,320	33,000	34,660
PM	33,610	37,280	33,680	37,770	38,580
Daily	422,800	473,500	435,200	468,900	497,600
South Screenline (South of S. King Street)					
AM	33,410	36,330	32,440	36,080	37,510
PM	37,580	42,340	37,640	42,130	43,630
Daily	470,500	534,900	531,900	536,800	561,600
Central Screenline (North of Seneca Street)					
AM	30,980	33,230	28,420	32,880	34,060
PM	34,590	37,190	31,790	36,790	37,850
Daily	409,700	444,800	387,600	440,400	453,900
North Screenline (North of Thomas Street)					
AM	36,720	39,550	35,910	39,360	40,650
PM	40,280	43,290	39,920	43,690	46,370
Daily	478,700	517,800	473,500	523,600	558,600

2

3 **Spokane Screenline**

4 For the Spokane screenline, the 2015 Baseline and the 2015 Project volumes are
 5 projected to be similar, indicating that both scenarios would accommodate the
 6 same number of trips. Volumes for both scenarios were also higher than for
 7 existing conditions (2005), with an increase of 6 to 7 percent in the AM peak
 8 period and 11 to 12 percent in both the PM peak and daily periods.

9 Under the Viaduct Closed (No Build Alternative), peak demand at this screenline
 10 was about 11 percent less and the daily volume was 8 percent less than for the
 11 2015 Baseline and 2015 Project scenarios. This was likely the result of an overall
 12 redistribution of trips and a reduction in demand to and through downtown
 13 Seattle due to reduced capacity through the central waterfront. While the total
 14 volumes decrease in the Viaduct Closed (No Build Alternative), the arterials in
 15 the 2015 Baseline and 2015 Project scenarios handle much of the demand, with
 16 volume increases of 26 percent and 21 percent, respectively.

17

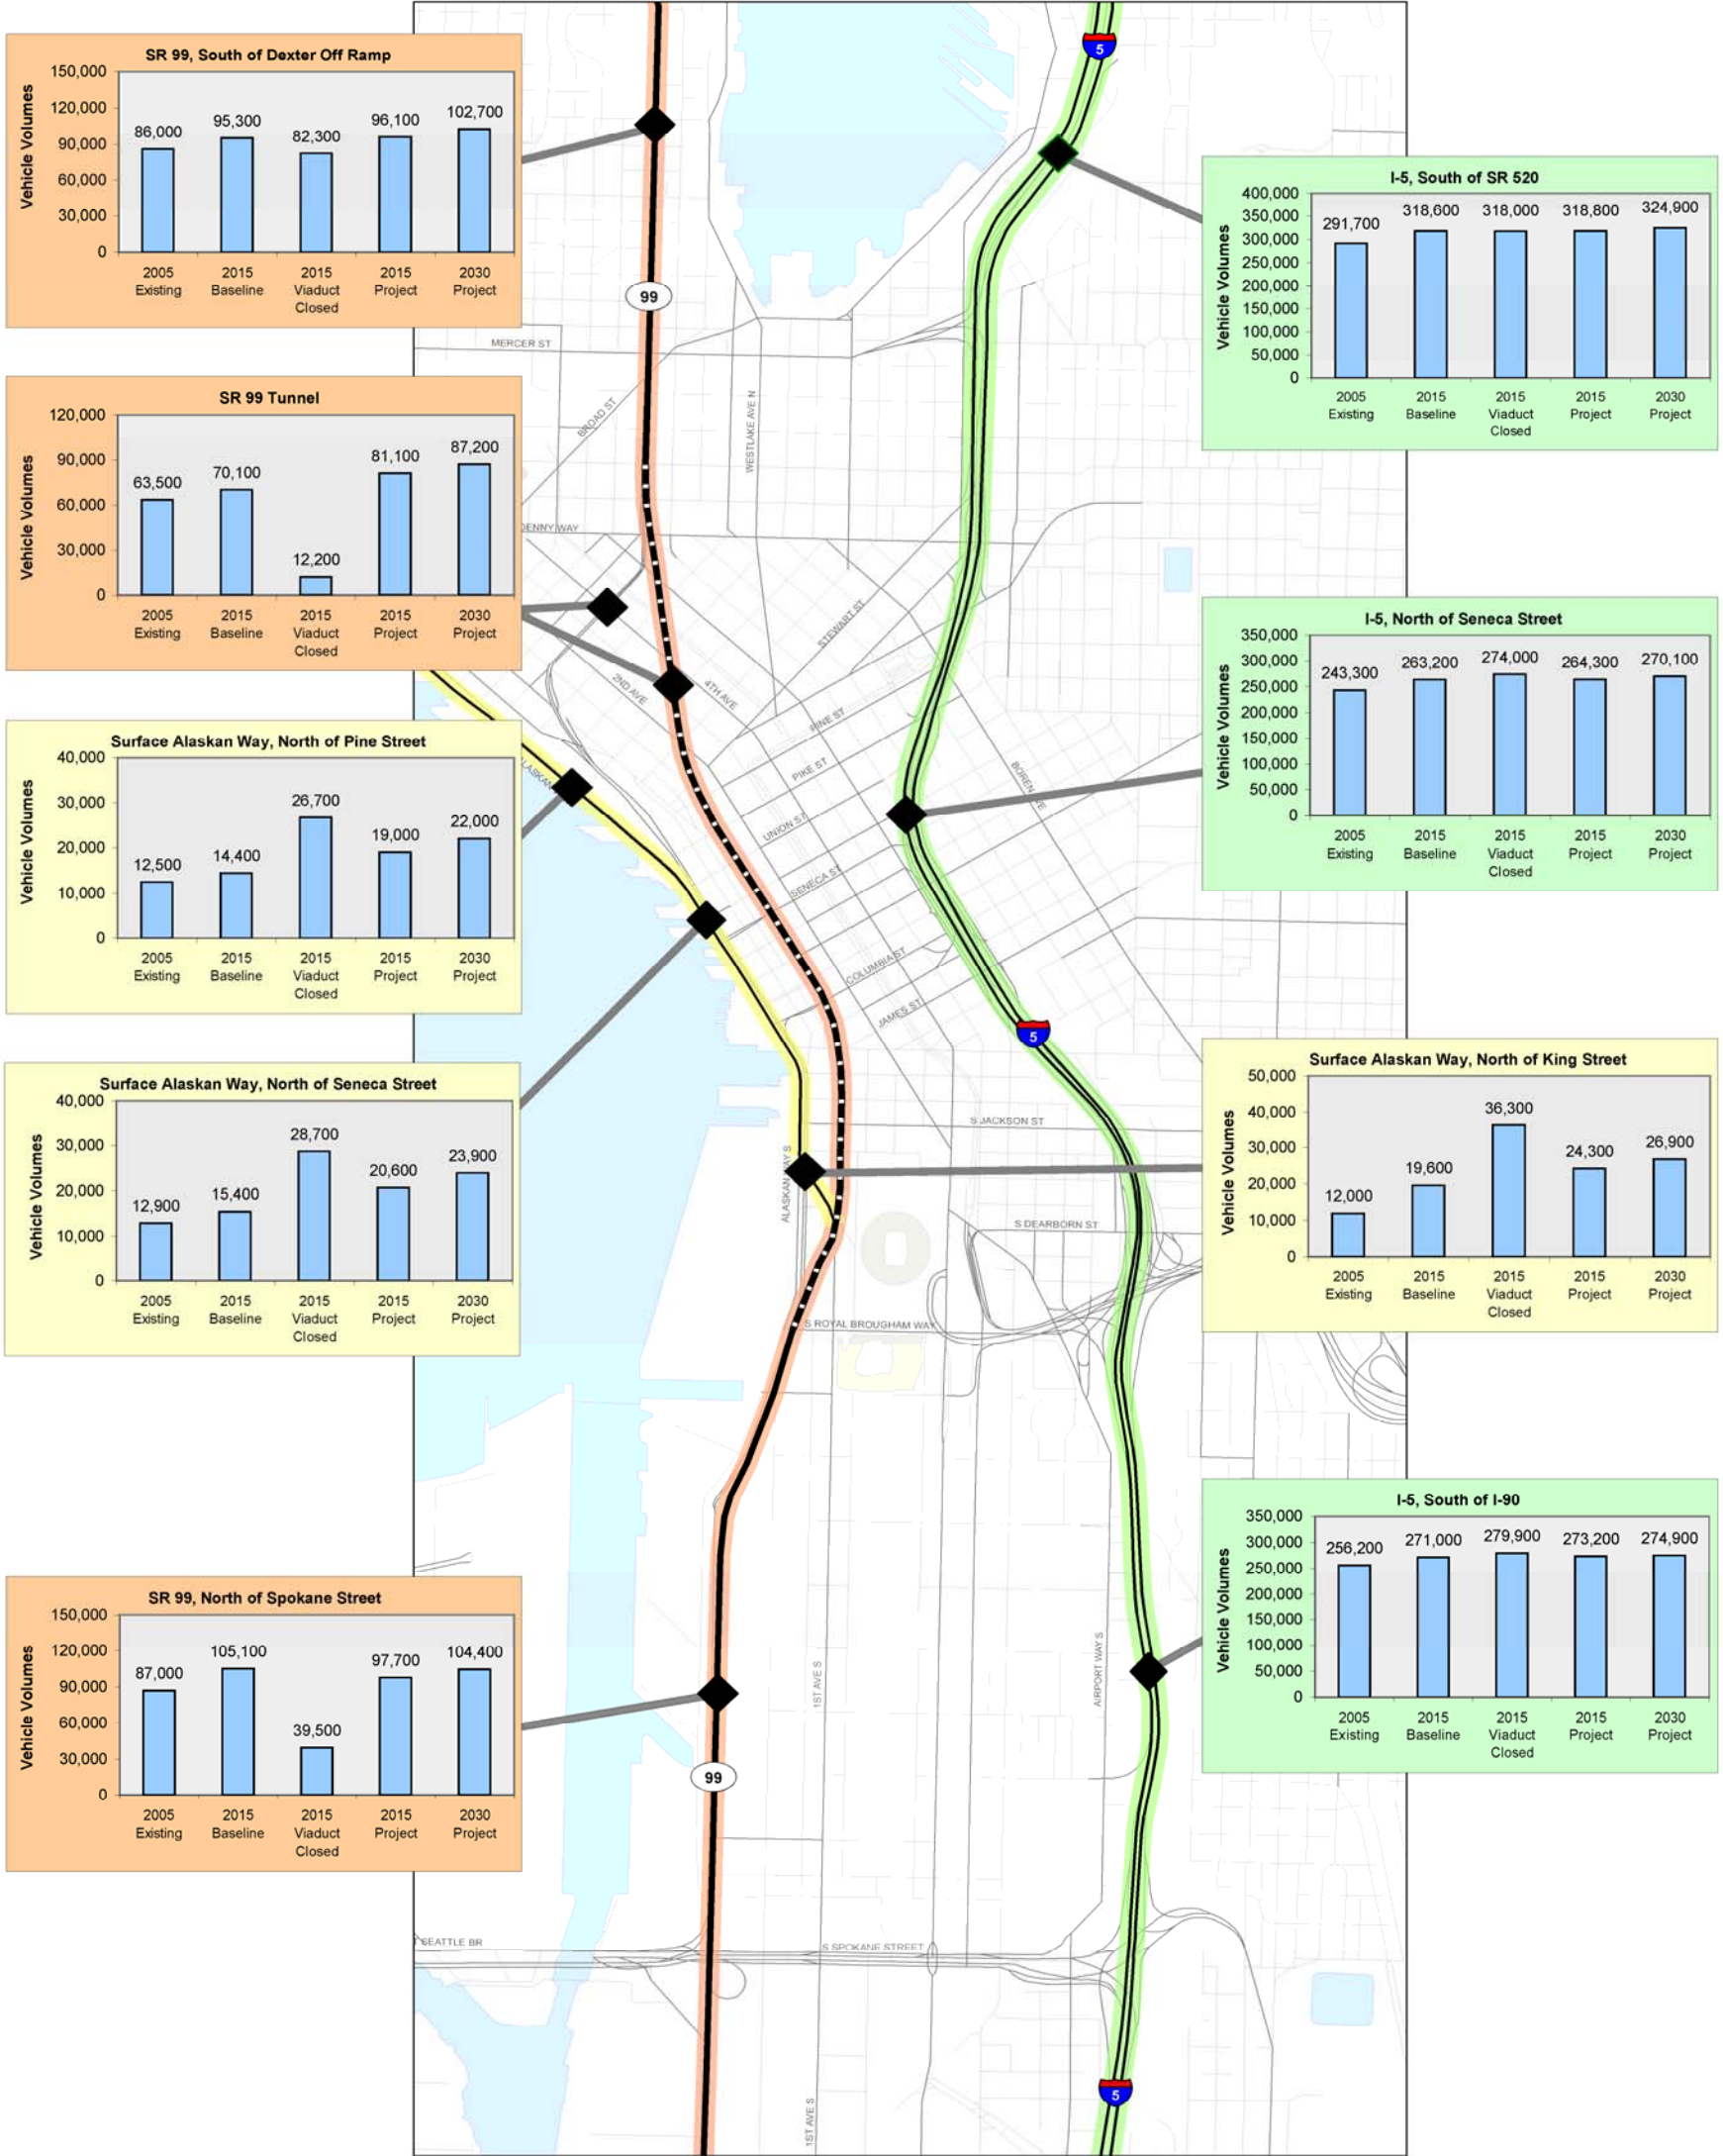

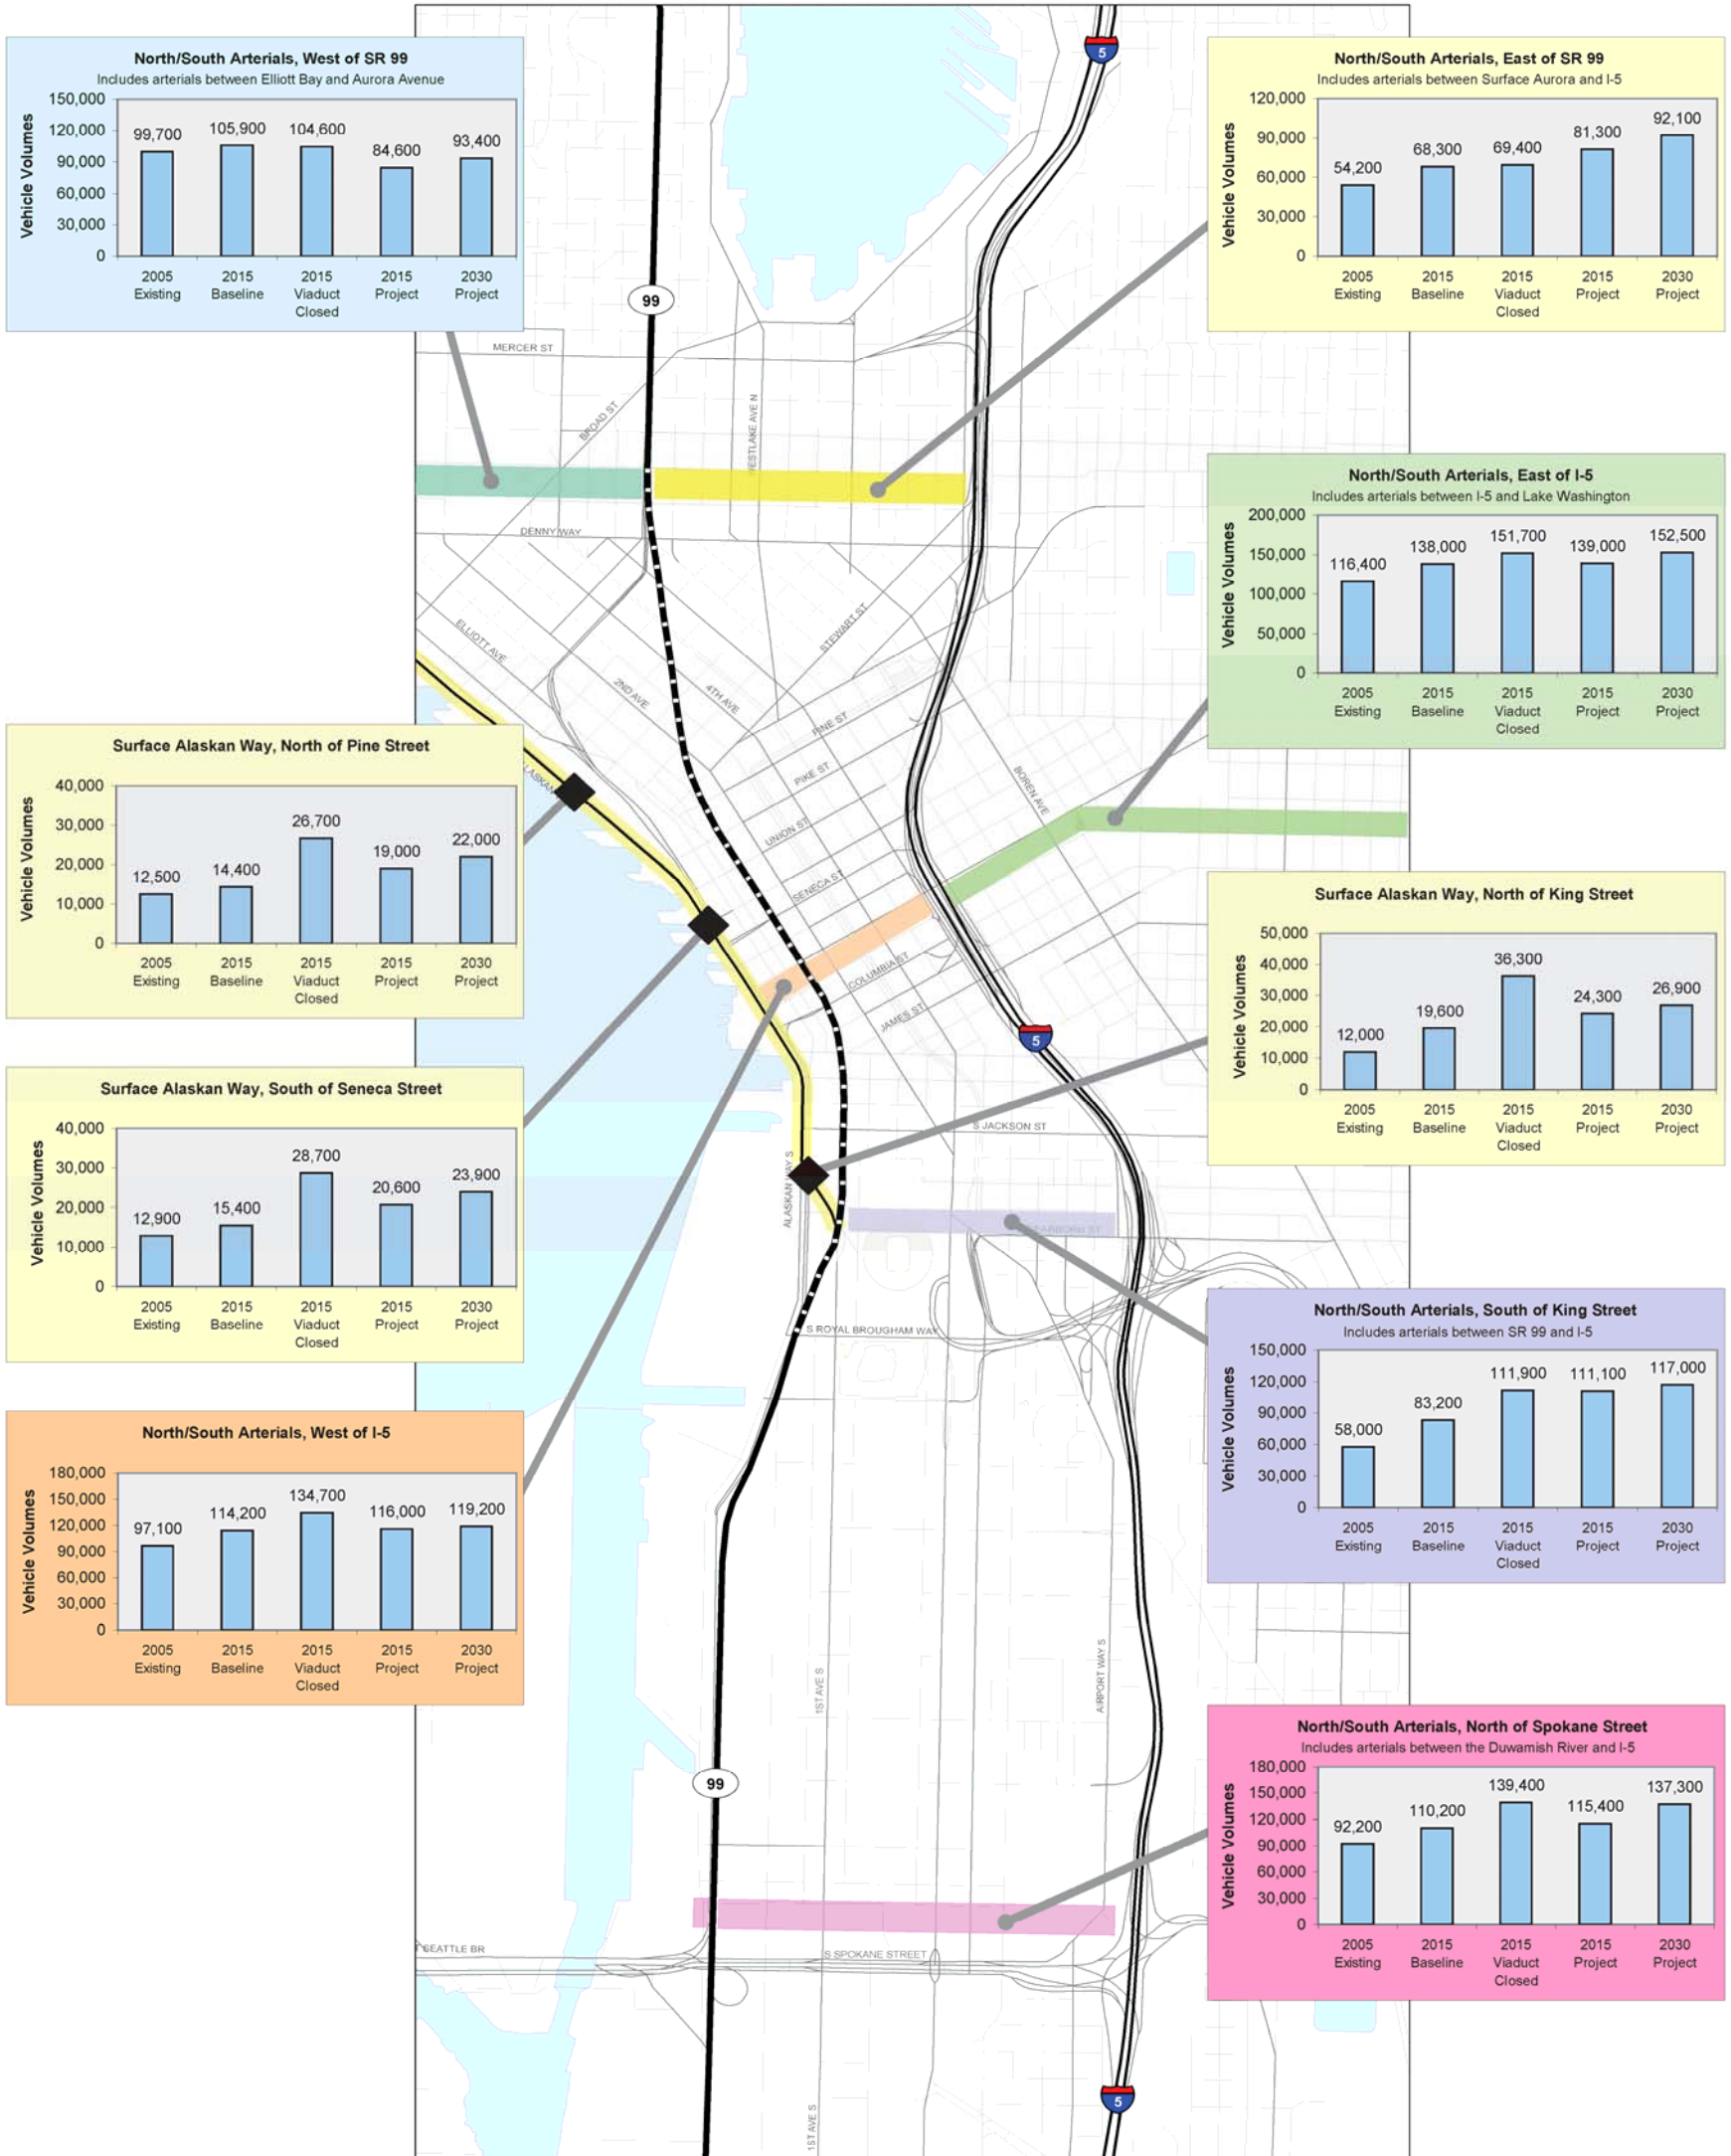

Exhibit 5-6
Daily Vehicle Volumes on I-5, SR 99,
and Surface Alaskan Way

Arterial screenlines do not include I-5 or SR 99 volumes

Exhibit 5-7
Daily Vehicle Volumes on Arterials

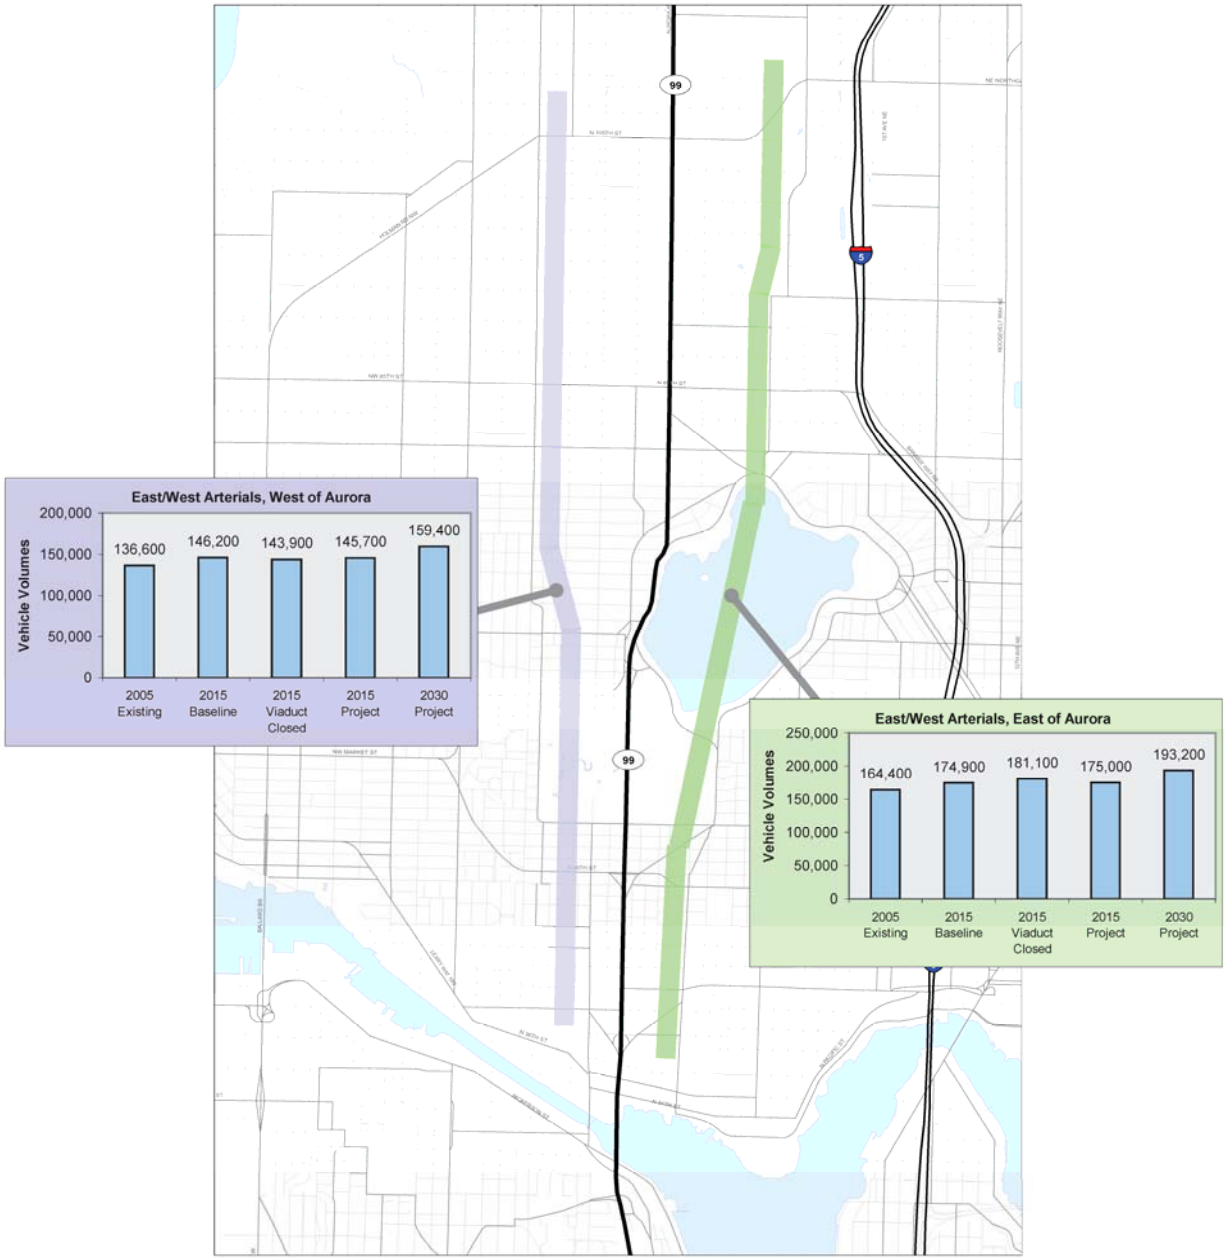

Exhibit 5-8
Daily Vehicle Volumes on Arterials
In North Seattle

1 **South Screenline**

2 For the south screenline, the 2015 Baseline scenario is projected to be slightly
3 higher in the AM peak period (almost 9 percent) and in the PM peak period
4 (almost 13 percent) than for existing conditions (2005). Daily screenline totals are
5 expected to increase by almost 14 percent.

6 The 2015 Project scenario is estimated to have similar overall volumes as the 2015
7 Baseline scenario (see Exhibit 5-5), indicating that it accommodates the same
8 number of trips. However, as can be seen in Exhibit 5-7, for the arterial screenline
9 in the same location and for Alaskan Way volumes north of S. King Street, the
10 volumes are expected to be redistributed such that the surface arterials under the
11 2015 Project carry a higher proportion of the overall screenline traffic, and SR 99 a
12 lower proportion, in comparison to the 2015 Baseline. This is due to the
13 relocation of the downtown access from the midtown ramps to the stadium
14 ramps, and the Ballard/Interbay access from the Elliott/Western ramps also to the
15 stadium ramps; the 2015 Project scenario directs more traffic to the surface
16 arterials at this location than the 2015 Baseline scenario.

17 Under the Viaduct Closed (No Build Alternative), peak period demand at this
18 screenline was about 12 percent less than with the comparable 2015 Baseline and
19 2015 Project scenarios. This was likely the result of an overall redistribution of
20 trips and a reduction in demand to and through downtown Seattle due to
21 reduced capacity through the central waterfront. Overall, daily screenline
22 volumes were about equal between the 2015 Baseline, 2015 Project, and the 2015
23 Viaduct Closed (No Build Alternative) scenarios. In addition, vehicle demand
24 displaced off of the Alaskan Way Viaduct under the Viaduct Closed (No Build
25 Alternative) is showing up on parallel arterials, such as Alaskan Way S. Under
26 the Viaduct Closed (No Build Alternative), daily vehicle volumes on Alaskan
27 Way S. increase by about 225 percent over the 2015 Baseline levels. Peak period
28 vehicle volumes here are over 240 higher under the Viaduct Closed (No Build
29 Alternative) than under the 2015 Baseline scenario.

30 **Central Screenline**

31 2015 Project vehicle volumes at this screenline are very close to the 2015 Baseline
32 volumes for the peak and daily travel periods (within 1 percent), which indicates
33 that the Bored Tunnel Alternative provides capacity comparable to the Alaskan
34 Way Viaduct (2015 Baseline). However, similar to the south screenline, the
35 volumes are expected to be redistributed such that the surface arterials under the
36 2015 Project scenario carry a higher proportion of the overall screenline traffic,
37 and SR 99 a lower proportion, in comparison to the 2015 Baseline. This is due
38 primarily to the relocation of the Ballard/Interbay access from the Elliott/Western

1 ramps to the stadium ramps in the 2015 Project scenario, which directs more
2 traffic to Alaskan Way than the 2015 Baseline scenario.

3 Volumes were about the same on north-south arterials east of I-5 for both the 2015
4 Project and the 2015 Baseline scenarios. Both of these scenarios showed almost
5 the same amount of traffic on I-5 for both the peak and daily travel periods as
6 well, indicating little shift in traffic to I-5.

7 As shown in Exhibit 5-5, the scenario with the highest peak period and daily
8 volumes remained the 2030 Program scenario. Volumes for this scenario are
9 about 3 percent higher than for the 2015 Project scenario for all time periods.
10 They are also about 2 percent higher than in the 2015 Baseline scenario, reflecting
11 that the 2030 Project scenario would experience very marginal growth in vehicle
12 volumes at this location.

13 The scenario with the lowest total daily and peak period screenline vehicle
14 volumes is the Viaduct Closed (No Build Alternative). Volumes are lowest here
15 due to the removal of the Alaskan Way Viaduct and the resulting redistribution
16 of traffic on already congested roadways, which results in some trips not
17 traveling through the downtown area.

18 While the estimated vehicle volumes at screenlines in the aggregate reflect one
19 picture of vehicle demand on downtown streets, individual streets behaved much
20 differently. As shown in Exhibit 5-6, Alaskan Way surface street consistently
21 carried the most traffic during the AM and PM peak and daily periods under the
22 Viaduct Closed (No Build Alternative). This was the case at all the locations
23 evaluated along the waterfront. As shown in Exhibit 5-7, this phenomenon also
24 carried to the north-south screenline west of I-5 (south of Madison Street), as
25 these streets also carried higher vehicle volumes than were found in any other
26 alternative. The higher volumes on Alaskan Way and the other north-south
27 arterials under the Viaduct Closed (No Build Alternative) are due to the fact that
28 these streets would need to absorb all traffic diverted from the (now closed)
29 Alaskan Way Viaduct (SR 99).

30 Vehicle volume differences were less pronounced for those north-south arterials
31 located east of I-5 than for those located on the west side of the freeway. As
32 shown in Exhibit 5-7, daily vehicle volumes were 18 percent higher for the
33 Viaduct Closed (No Build Alternative) than for the Baseline scenario for those
34 arterials west of I-5, while Viaduct Closed (No Build Alternative) volumes were
35 slightly less than 10 percent higher than Baseline volumes for the arterials east of
36 I-5.

1 **North Screenline**

2 2015 Project daily vehicle volumes for north-south arterials on the west side of
3 SR 99 (see Exhibit 5-7) show a 20 percent decrease over the 2015 Baseline levels.
4 This change is more indicative of where the screenline is placed in relation to the
5 street network than a true decrease of trips through this area. In the 2015 Baseline
6 scenario, many trips traveling between the South Lake Union area and Elliott
7 Avenue N. use Broad Street and Denny Way and then travel north on Elliott
8 Avenue N., effectively crossing the north screenline twice. Because the 2015
9 Project scenario removes Broad Street between Ninth Avenue N. and Taylor
10 Avenue N., and Mercer Street is made two-way between Ninth Avenue N. and
11 Fifth Avenue N., these same trips between the South Lake Union area and Elliott
12 Avenue N. are projected instead to stay on Mercer and Roy Streets in the 2015
13 Project and would not be counted at all in the north screenline volumes. On the
14 other hand, daily volumes vary greatly on north-south arterials east of SR 99. The
15 2015 Project daily volumes are about 19 percent higher than those for the 2015
16 Baseline and Viaduct Closed (No Build Alternative) scenarios. This is likely due
17 to improved east-west connections across Aurora Avenue (i.e., John, Thomas, and
18 Harrison Streets as well as two-way Mercer Street), which allows for greater use
19 of the grid network in the South Lake Union area.

20 **North Seattle Screenlines**

21 Vehicle volumes on east-west arterials north of the Ship Canal are very similar
22 across all 2015 scenarios (see Exhibit 5-8). Volume changes across these
23 screenlines are projected to be less than 0.5 percent between the 2015 Baseline and
24 2015 Project scenarios, indicating that diversion from the 15th Avenue N.W./Elliott
25 Avenue N. corridor to SR 99 or I-5 is not expected to occur. The largest impact on
26 vehicle volumes is with the Viaduct Closed (No Build Alternative), which shows
27 a 3 percent increase over 2015 Baseline levels on arterials between Aurora Avenue
28 and I-5, likely due to diversion of vehicles to I-5 from SR 99 to access destinations
29 downtown and southward.

30 **5.1.6 Person Throughput**

31 Person throughput is a measure of the total number of persons traveling on a
32 given transportation facility. Analysts use person-trips to measure the number of
33 people, rather than vehicles, which travel on the transportation system. Increased
34 use of transit or carpools can increase the overall number of people conveyed,
35 even if vehicle traffic does not increase.

36 This evaluation compares the total number of persons carried by the three major
37 east-west screenlines in the study area. The evaluation describes AM and PM
38 peak periods and daily totals for the 2015 Baseline and Project and the 2030

1 Project scenarios. Exhibit 5-9 provides a summary table of the person throughput
 2 by screenline for the study area.

3 **Key Findings**

- 4 • As reflected in all Center City screenlines, there would be a slight
 5 reduction in 2015 Viaduct Closed (No Build Alternative) person
 6 throughput in comparison to the respective 2015 Baseline and Project
 7 scenarios. This was likely the result of the removal of the capacity
 8 provided by the Alaskan Way Viaduct and redistribution of some trips to
 9 avoid traveling on already congested parallel facilities through downtown
 10 (i.e., downtown arterials and I-5).

11 **Exhibit 5-9. Model-Estimated Daily Person Throughput (Person-Trips)**

	2005 Existing	2015 Baseline	Viaduct Closed (No Build Alternative)	2015 Project	2030 Project
South Screenline (South of S. King Street)					
AM	45,690	54,730	49,950	54,000	65,350
PM	55,140	67,480	61,110	66,630	79,060
Daily	644,680	782,900	771,600	776,940	883,590
Central Screenline (North of Seneca Street)					
AM	46,090	52,870	46,970	52,330	60,360
PM	54,530	62,310	54,900	61,530	69,840
Daily	585,120	659,170	579,900	650,270	746,610
North Screenline (North of Thomas Street)					
AM	53,190	59,370	55,440	59,120	67,730
PM	61,990	69,460	65,200	70,030	80,770
Daily	672,920	752,450	698,420	760,840	866,730

12

13 **South Screenline**

14 During the 2015 Baseline scenario AM peak period, this screenline would carry
 15 almost 55,000 person trips, while during the PM peak period this screenline is
 16 forecasted to carry over 67,000 person trips. There are almost 783,000 daily
 17 person trips forecasted to be carried on the south screenline under 2015 Baseline
 18 conditions. Both the 2015 Baseline and 2015 Project scenarios carry virtually the
 19 same number of persons at this screenline location. The 2015 Viaduct Closed (No
 20 Build Alternative) carries slightly fewer person trips than the Baseline and Project
 21 scenarios, which is likely the result of the removal of the Alaskan Way Viaduct
 22 and redistribution of its traffic onto already congested north-south arterials and

1 I-5. By 2030, under the Project scenario, the south screenline would carry almost
2 834,000 daily persons, which is about 11 percent over 2015 Baseline levels. The
3 AM and PM peak periods would carry slightly higher percentages of total person
4 trips for the 2030 Project scenario than for the 2015 Baseline scenario.

5 Central Screenline

6 The central screenline carries about 659,000 daily persons under the 2015 Baseline
7 conditions. During the AM peak period, this screenline would carry over 53,000
8 persons, while during the PM peak period it is forecasted to carry almost 62,000
9 person trips. Both the 2015 Baseline and 2015 Project scenarios forecast virtually
10 the same number of persons at this screenline location. By 2030, the Project
11 scenario would carry almost 747,000 daily persons, which is about 13 percent over
12 the 2015 Baseline levels. During the AM peak period, the 2030 Project scenario
13 would carry over 14 percent more people than the comparable period under the
14 2015 Baseline scenario. In the PM peak period, the 2030 Project would carry over
15 12 percent more people than the comparable period under the 2015 Baseline.

16 North Screenline

17 The north screenline would carry about 752,000 daily persons under the 2015
18 Baseline conditions. During the AM peak period, this screenline would carry
19 over 59,000 persons, while during the PM peak period it would carry almost
20 70,000 person trips. Both the 2015 Baseline and 2015 Project scenarios would
21 carry virtually the same number of persons at this screenline location. By 2030,
22 under the Project scenario, the screenline would carry almost 867,000 daily
23 persons, which is about 15 percent over the 2015 Baseline levels. During the AM
24 peak period under the 2030 Project scenario, this screenline would carry over
25 14 percent more people than during the comparable period under the 2015
26 Baseline scenario. In the PM peak period under the 2030 Project scenario, this
27 screenline would carry over 16 percent more people than during the comparable
28 period under the 2015 Baseline scenario.

29 5.2 Traffic Operations on SR 99

30 Mainline traffic conditions and ramp interactions for the SR 99 corridor in terms
31 of AM and PM peak hour volumes, travel speeds and LOS are presented in this
32 section for key mainline segments and related on-/off-ramps. This discussion
33 focuses on the three applicable scenarios for operational impacts represented by
34 2015 Baseline, 2015 Project and 2030 Project conditions.

1 Key Findings

- 2 • Baseline volumes show peak period directionality, with higher volumes
3 inbound to downtown during the AM peak hour, and the reverse during
4 the PM peak hour.
- 5 • The function of the midtown ramps in the Baseline scenario is
6 supplemented by the stadium area ramps to/from the south, resulting in
7 less traffic using the mid-town ramps as compared to existing conditions.
- 8 • Because of the reduced capacity for corridor through trips, the Viaduct
9 Closed (No Build Alternative) scenario is expected to have considerably
10 lower volumes on SR 99 just north and south of downtown as compared
11 to the Baseline and the Bored Tunnel Alternative.
- 12 • The Bored Tunnel Alternative changes access to/from SR 99 and
13 downtown. Ramps in the stadium area would provide the connection to
14 downtown from the south, while the ramps to/from Aurora Avenue at
15 Harrison Street would provide the access route in the north end. The
16 stadium area ramps are projected to carry higher volumes than the
17 corresponding existing ramps at Seneca and Columbia Streets in the
18 Baseline scenario. This is due to the absence of the Elliott/Western ramps,
19 resulting in a projected increase in vehicles travelling on Alaskan Way
20 surface street and then accessing SR 99 via the stadium area ramps.
- 21 • Volumes on SR 99 through the midtown area are projected to be lower
22 than in the Baseline scenario. However, as described previously,
23 screenline analysis shows that these trips are accommodated elsewhere in
24 the system, with the result that the total volume of trips carried by the
25 system is approximately the same.
- 26 • Most segments of the SR 99 mainline in the 2015 Baseline scenario are
27 expected to operate at LOS E or F. Conditions in the Viaduct Closed (No
28 Build Alternative) scenario are expected to be worse, with extremely high
29 travel times for those travelling through the CBD.
- 30 • With the 2015 Project scenario, traffic operations on the mainline are
31 expected to be similar to or slightly improved in comparison with the 2015
32 Baseline, with segments generally operating at LOS D or E. Similarly,
33 travel speeds are expected to be higher with the 2015 Project scenario than
34 with 2015 Baseline scenario, and substantially higher than in the Viaduct
35 Closed (No Build Alternative) scenario.
- 36 • With the 2030 Project scenario, traffic operations on the mainline are
37 expected to worsen slightly compared to the 2015 Project scenario, with
38 segments operating at LOS D to F due to increased demand. Travel
39 speeds are also expected to decrease slightly compared to the 2015 Project.

1 5.2.1 Alaskan Way Viaduct Mainline and Ramp Volumes

2 This section describes the AM peak hour, PM peak hour, and daily traffic volume
3 estimates for the 2015 Viaduct Closed (No Build Alternative), 2015 Baseline, and 2015
4 and 2030 Project scenarios; specifically, these estimates for each connection to/from
5 SR 99 (ramps or side streets) and for each mainline segment (section of SR 99 between
6 connections) are discussed in detail below.

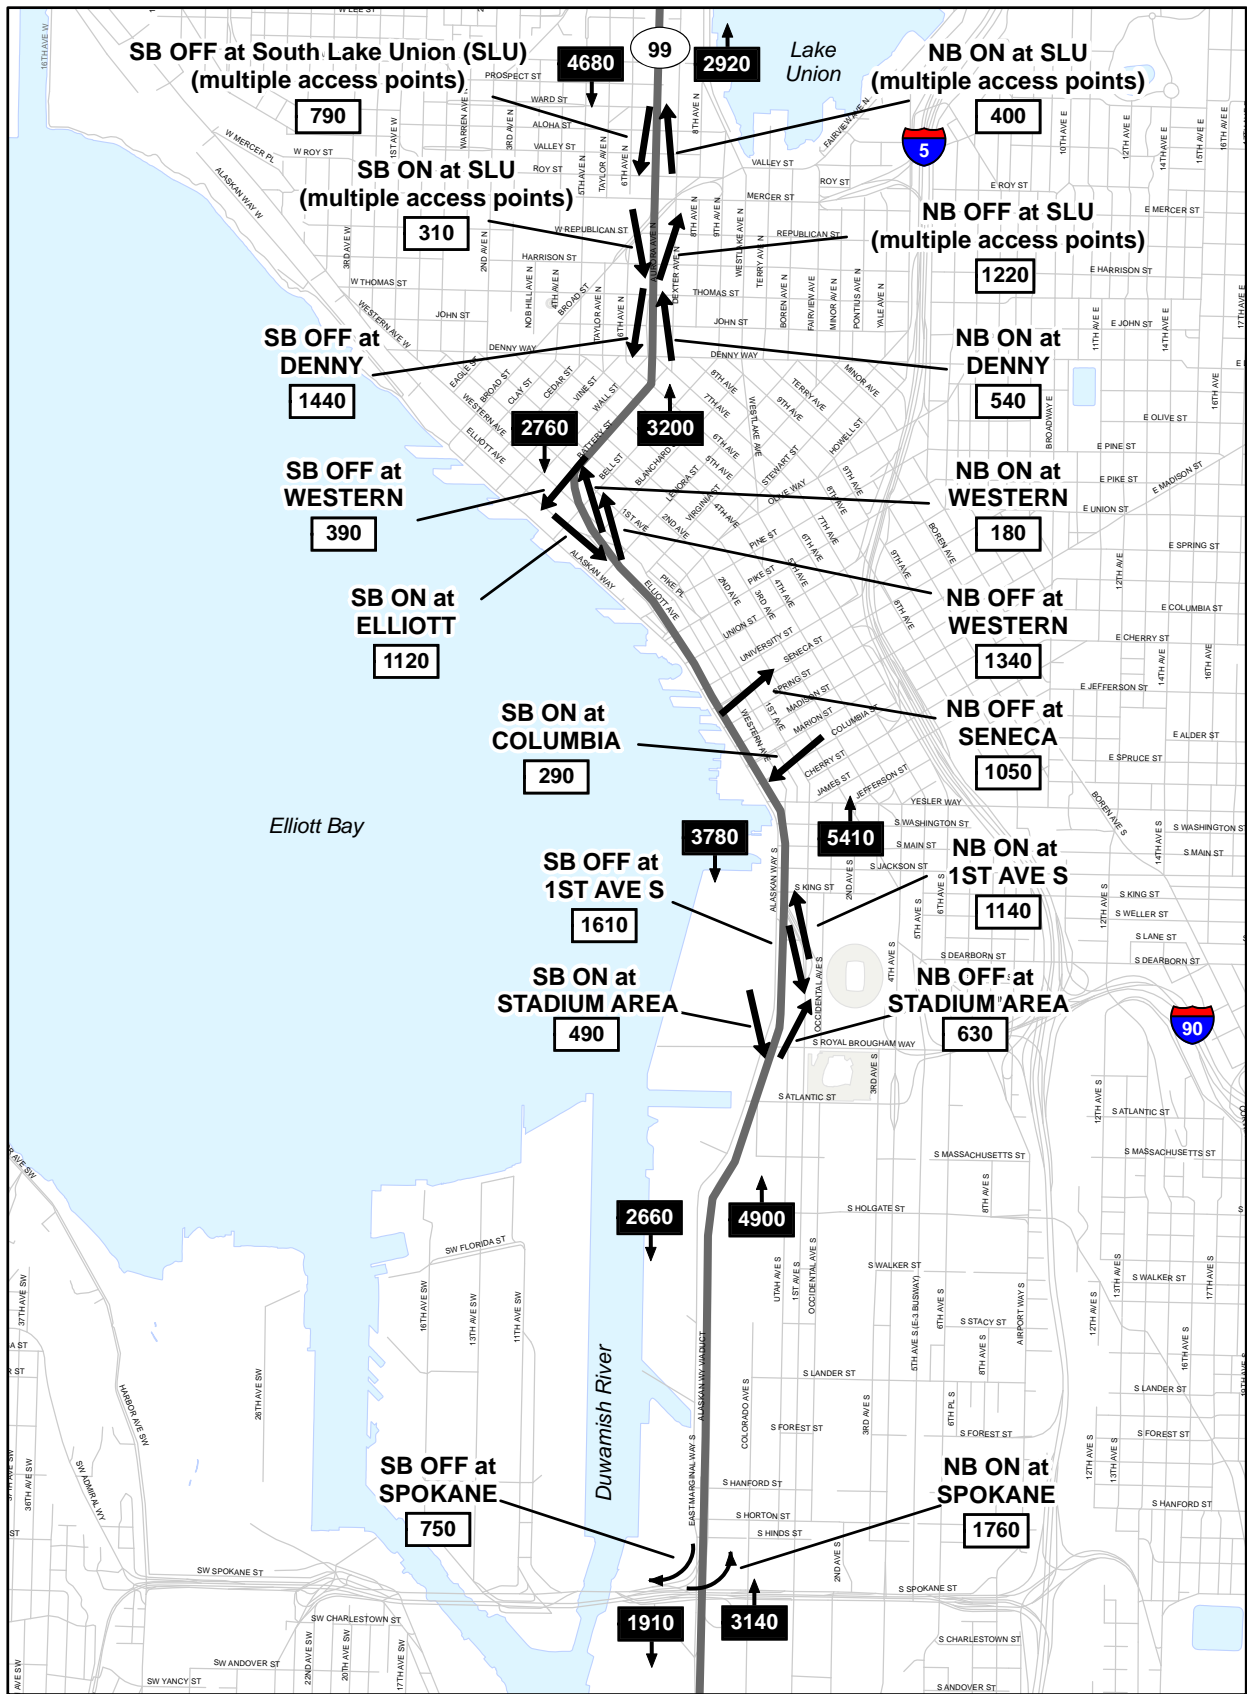

7 AM Peak Hour

8 As with most transportation facilities, traffic volumes on the SR 99 corridor are generally
9 the most pronounced during weekday commuting hours. In the morning, peak hour
10 traffic volumes on SR 99 are fairly directional, with heavier volumes entering the central
11 downtown area from all directions. Exhibits 5-10, 5-11, and 5-12 show the volumes in
12 the AM peak hour for the Baseline, 2015 Project, and 2030 Project scenarios, respectively.

13 2015 Baseline

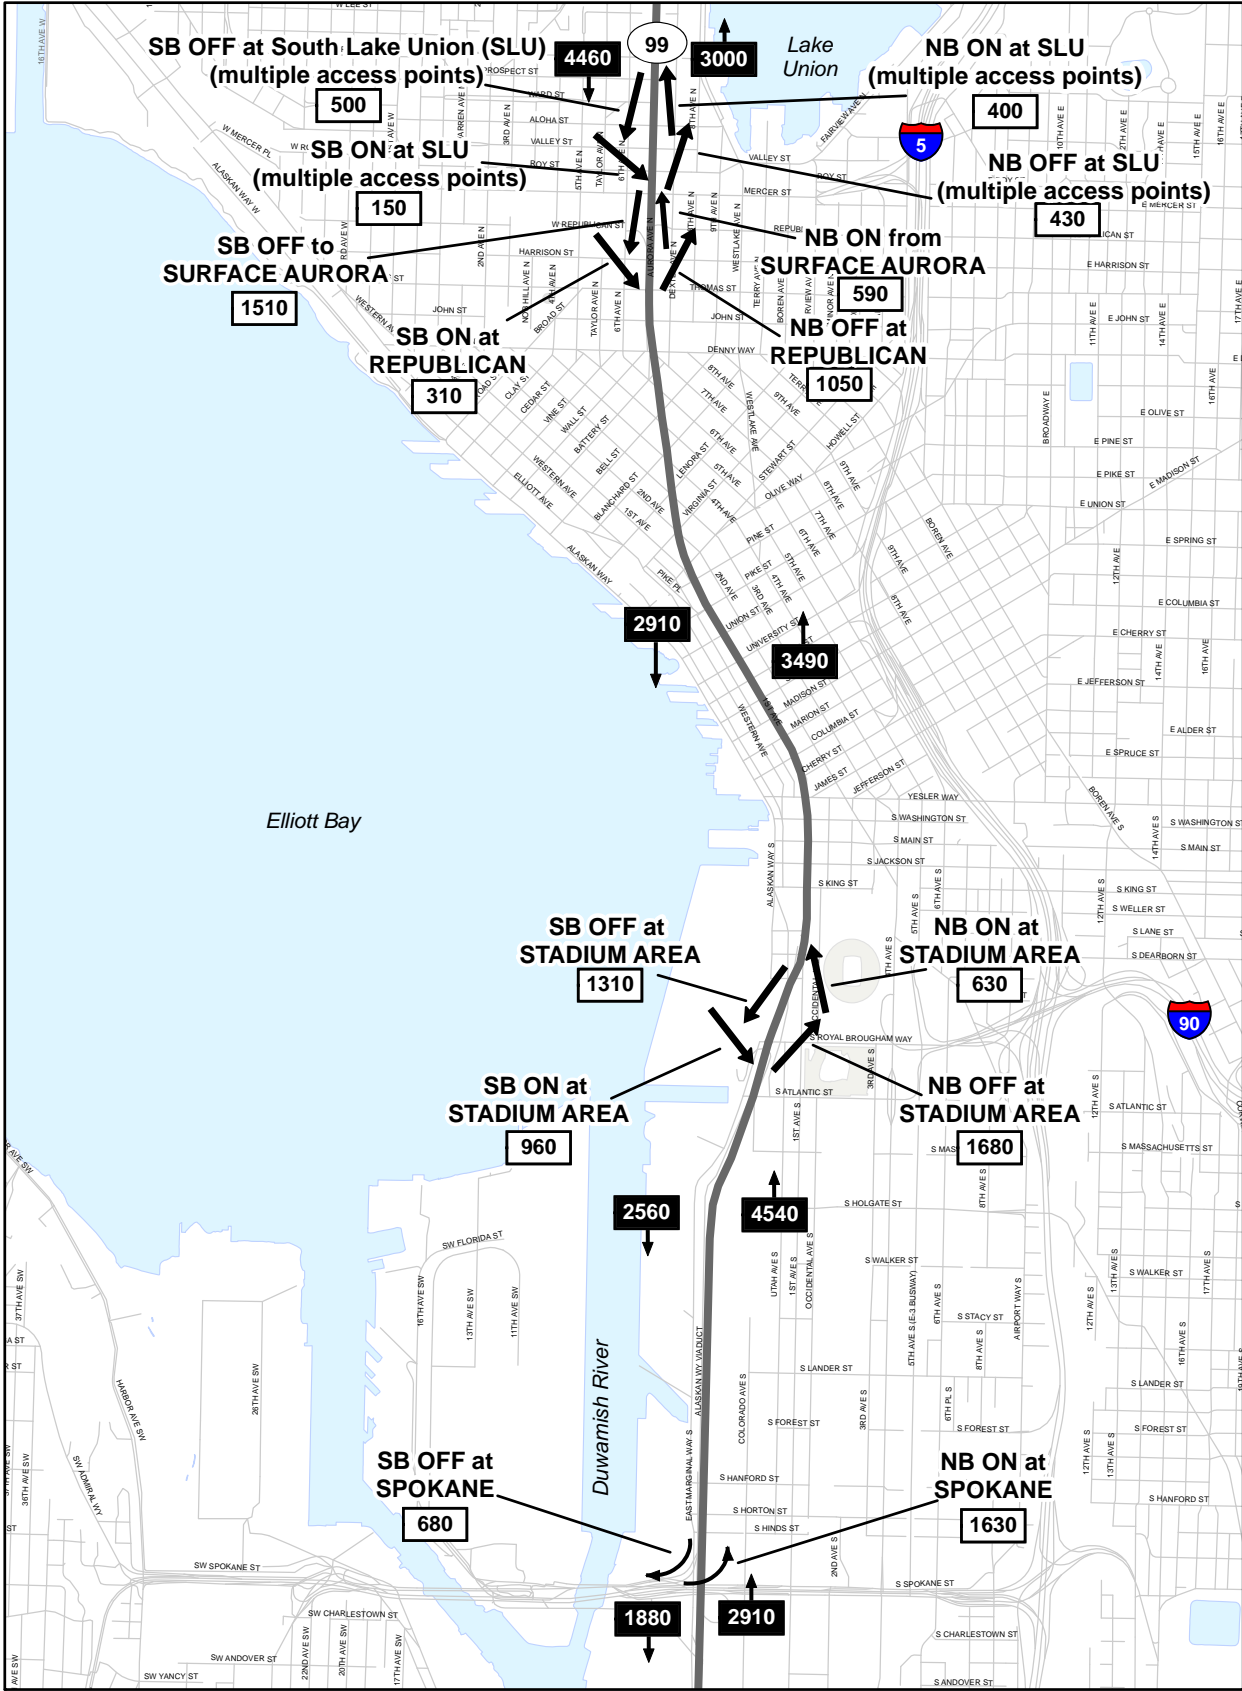

14 The downtown ramps providing access to and from the south show more vehicles
15 exiting northbound SR 99 at Seneca Street (1,050 vehicles) than entering southbound
16 SR 99 at Columbia Street (290 vehicles). AM peak hour mainline ramp volumes
17 forecasted for the Baseline are shown in Exhibit 5-10. The First Avenue S. ramps show
18 similar directionality, with 1,610 vehicles exiting southbound SR 99 in the morning but
19 only 490 vehicles entering northbound to SR 99. South of downtown and the stadium
20 area, mainline SR 99 volumes are considerably higher in the northbound direction
21 (4,900 vehicles) than in the southbound direction (2,660 vehicles). At S. Spokane
22 Street, volumes entering northbound SR 99 from West Seattle (1,760 vehicles) are more
23 than double those exiting southbound SR 99 to West Seattle (630 vehicles). The
24 volumes on the ramps at Seneca and Columbia Streets are projected to be generally
25 lower than under existing conditions because of the new ramps at S. King Street,
26 which would serve a similar function.

27 At the north end of the study area, AM peak hour mainline volumes are projected to be
28 higher in the southbound direction (4,680 vehicles) than in the northbound direction
29 (2,920 vehicles), as more vehicles are entering the South Lake Union and downtown
30 areas. Southbound SR 99 off-ramp volumes at Denny Way (1,440 vehicles) exceed
31 those on the northbound on-ramp (540 vehicles). In the Battery Street Tunnel, the
32 northbound flow (3,200 vehicles) slightly exceeds the volume of southbound vehicles
33 (2,760 vehicles), though volumes are generally similar overall. The ramps at the south
34 end of the Battery Street Tunnel that provide access to and from the north show
35 directionality as well, with 390 vehicles exiting southbound SR 99 and only 180 vehicles
36 entering northbound SR 99. The Elliott/Western ramps to and from the south, however,
37 do not show the same level of directionality, with 1,120 vehicles entering southbound
38 SR 99 and 1,340 vehicles exiting northbound SR 99.

 and Ramp Volumes -
 2015 Project**

XXX Ramp Volumes
XXX SR 99 Mainline Volumes

**Exhibit 5-12
 AM Peak Hour Mainline
 and Ramp Volumes -
 2030 Project**

1 2015 Viaduct Closed (No Build Alternative)

2 As the viaduct is assumed to be closed in this scenario, no southbound traffic is
3 assumed to be on the facility between the Battery Street Tunnel off-ramp and the
4 S. King Street on-ramp. Similarly, no northbound traffic is assumed to be on the
5 facility between the S. King Street off-ramp and the Battery Street Tunnel on-ramp.

6 2015 Project

7 Compared with the 2015 Baseline, the 2015 Project (Bored Tunnel Alternative)
8 scenario changes access to/from SR 99 and downtown. Ramps in the stadium
9 area would provide the connection to downtown from the south, while the ramps
10 to/from SR 99 at Harrison Street (ultimately to/from Denny Way) would provide
11 the access route in the north end. The southbound stadium area on-ramp would
12 serve vehicles that would otherwise have used the on-ramp at Columbia Street. It
13 is expected to have higher volumes (960 vehicles) than the ramp at Columbia
14 Street (290 vehicles) under Baseline conditions, partly due to the fact that, with
15 the absence of the southbound on-ramp from Elliott Avenue, some traffic
16 traveling through the corridor from points northwest of the CBD would use this
17 entrance to travel further south. AM peak hour mainline ramp volumes
18 forecasted for the 2015 Bored Tunnel Alternative are shown in Exhibit 5-11.

19 Similar to southbound, the northbound stadium area off-ramp would serve vehicles
20 that would have otherwise used the Baseline ramp at Seneca Street. It is also
21 expected to have higher volumes (1,680 vehicles) than the Baseline ramp at Seneca
22 Street (1,050 vehicles). Also, similar to the southbound direction, this is partly due to
23 the absence of the northbound off-ramp to Western Avenue. The mainline volumes
24 in both directions south of the stadium area are similar under both Baseline and 2015
25 Project conditions.

26 The new downtown ramps providing access to and from the south show more
27 vehicles exiting northbound SR 99 at S. King Street (1,680 vehicles) than entering
28 southbound SR 99 (960 vehicles). The stadium ramps to and from the north show
29 similar directionality, with 1,310 vehicles exiting southbound SR 99 but only 630
30 vehicles entering northbound SR 99. As with Baseline conditions, in the areas south
31 of downtown and near the stadiums, mainline volumes are considerably higher in
32 the northbound direction (4,540 vehicles) than the southbound direction (2,560
33 vehicles). At S. Spokane Street, volumes entering northbound from West Seattle
34 (1,630 vehicles) are more than double those exiting southbound to West Seattle (600
35 vehicles).

36 The bored tunnel is projected to carry 2,910 vehicles southbound and 3,490 vehicles
37 northbound during the AM peak hour. These volumes are lower than under
38 Baseline conditions, with 3,490 southbound and 4,360 vehicles northbound through

1 midtown between the Elliott/Western and Seneca/Columbia ramps. Again, this is
2 because of the absence of the ramps at Elliott and Western Avenues. Many of the
3 trips that would have used those Baseline ramps are anticipated to instead travel
4 along the surface on Alaskan Way and other parallel streets. However, the bored
5 tunnel volumes are higher than the volumes in the Battery Street Tunnel under
6 Baseline conditions (2,760 vehicles southbound and 3,200 vehicles northbound), as
7 some through traffic that would otherwise use parallel routes is attracted to the
8 tunnel, including some vehicles that would have used the Elliott/Western ramps and
9 are anticipated to access SR 99 north of downtown via Mercer Street.

10 At the north end of the study area, mainline volumes are anticipated to be fairly
11 similar between Baseline and 2015 Project conditions, with 4,460 vehicles entering
12 downtown (southbound) under Project conditions, compared to 4,680 vehicles under
13 Baseline conditions. The Bored Tunnel Alternative does not include on-/off-ramps at
14 Elliott and Western Avenues, generally resulting in slightly higher ramp volumes in
15 the South Lake Union area in both directions compared to the Baseline. The higher
16 volumes to and from the south in this area result because some of the traffic from
17 northwest Seattle that previously used the Elliott/Western ramps to travel through
18 the corridor are expected to take Mercer Street to access the bored tunnel at the
19 Republican Street ramps.

20 2030 Project

21 The 2030 Project volume estimates are generally similar to 2015 Project forecasts,
22 with modest increases in volumes for some mainline and ramp segments. Vehicle
23 volumes in the bored tunnel are expected to increase to approximately 3,010 vehicles
24 southbound and 3,670 northbound. AM peak hour mainline ramp volumes
25 forecasted for the 2030 Project scenario are shown in Exhibit 5-12.

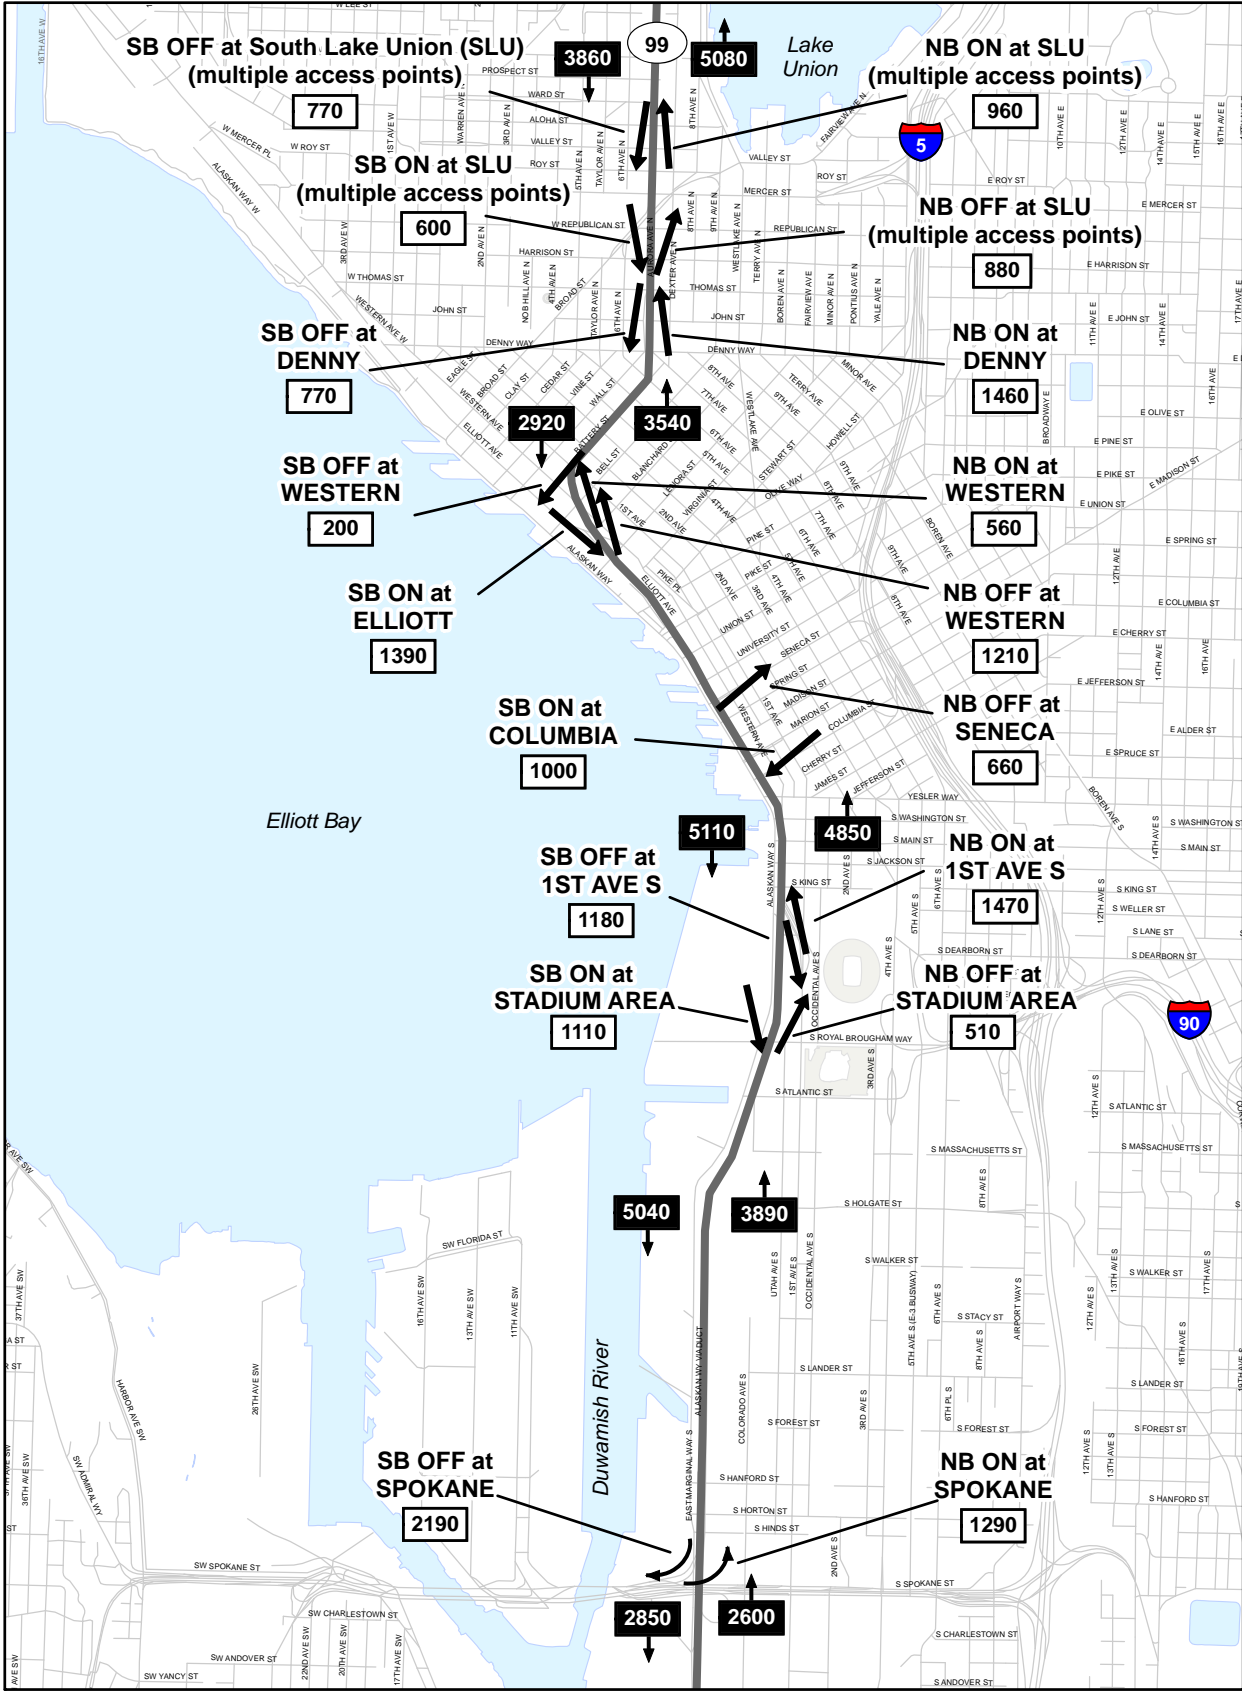

26 **PM Peak Hour**

27 Exhibits 5-13, 5-14, and 5-15 show the volumes in the PM peak hour for the
28 Baseline, 2015 Project, and 2030 Project scenarios, respectively.

29 2015 Baseline

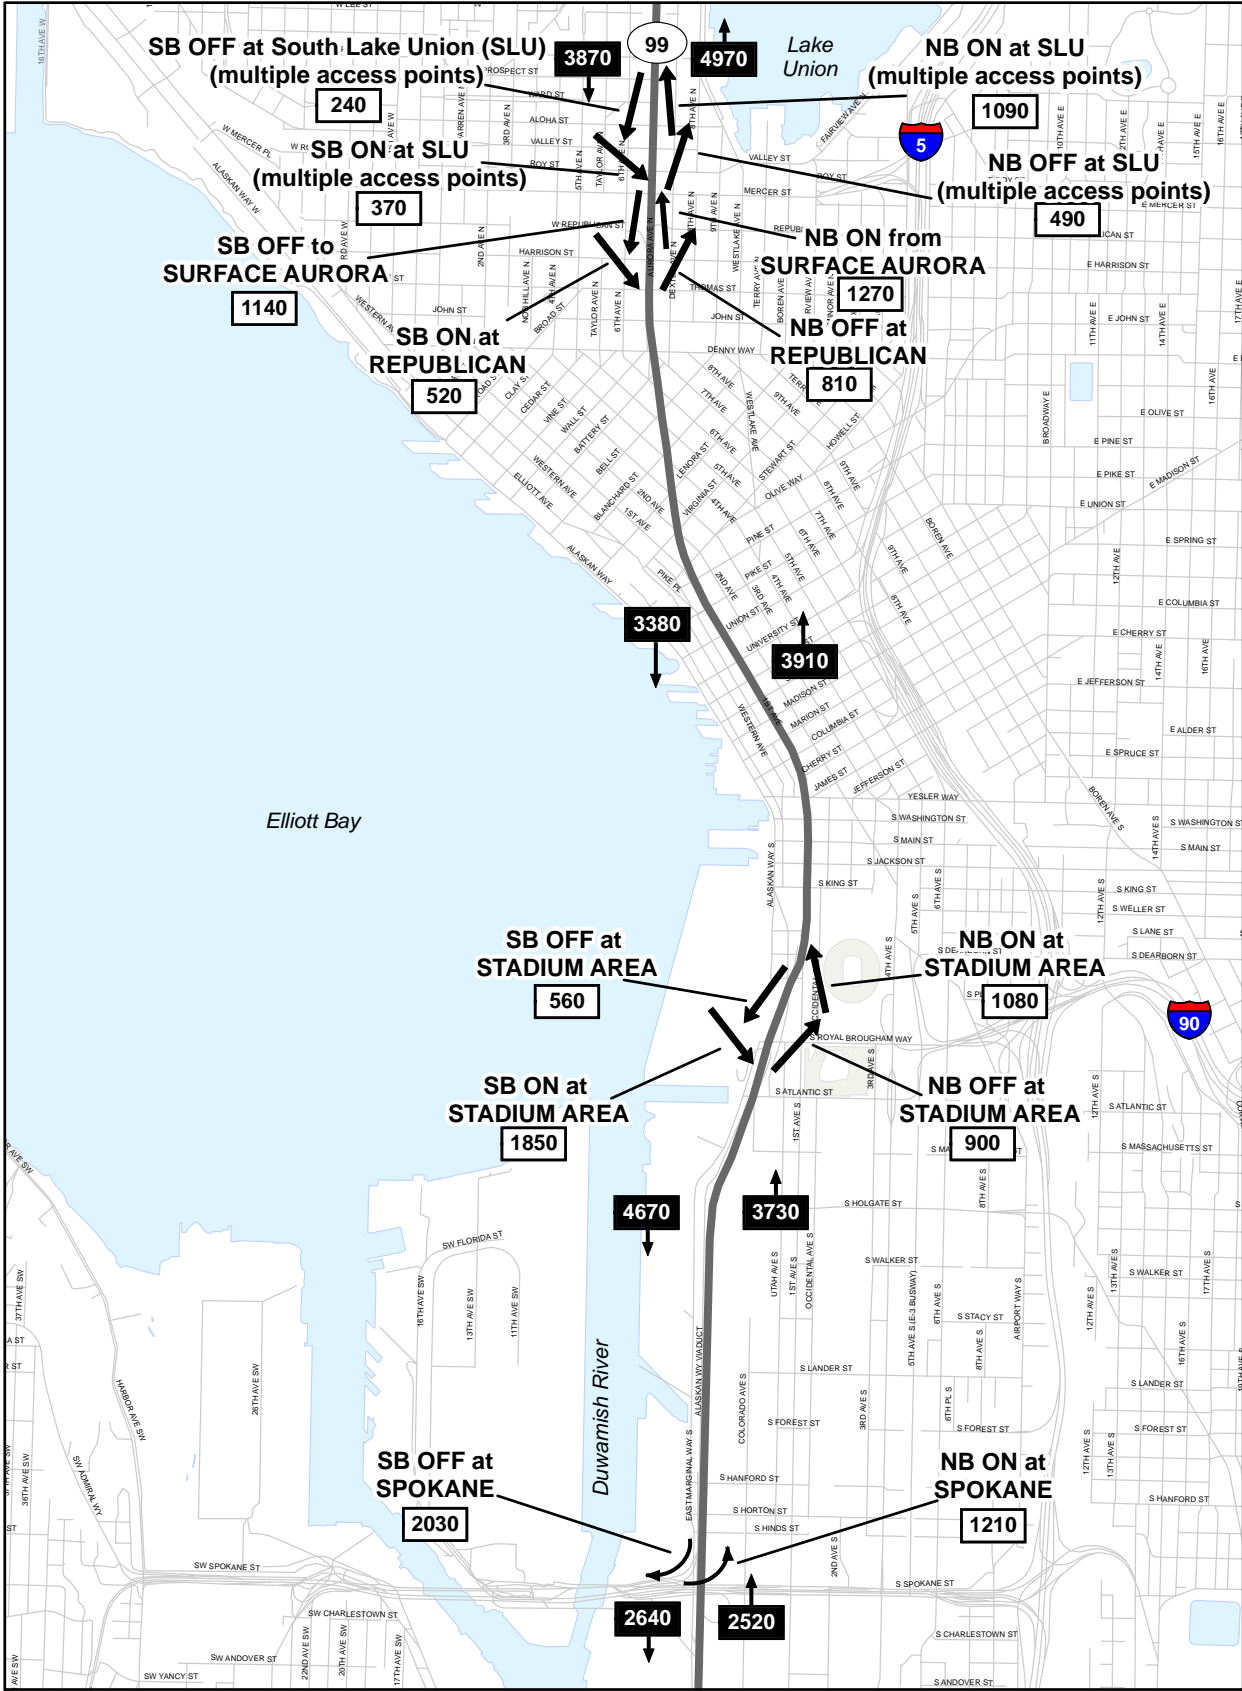

30 Similar to the AM peak, the PM peak hour traffic volumes along SR 99 are
31 directional (though generally not as pronounced as AM peak volumes), with heavier
32 volumes leaving the central downtown. PM peak hour mainline ramp volumes
33 forecasted for the Baseline scenario are shown in Exhibit 5-13.

34 The downtown ramps to and from the south show more vehicles entering
35 southbound SR 99 at Columbia Street (1,000 vehicles) than exiting northbound SR 99
36 at Seneca Street (660 vehicles). The First Avenue S. ramps show similar

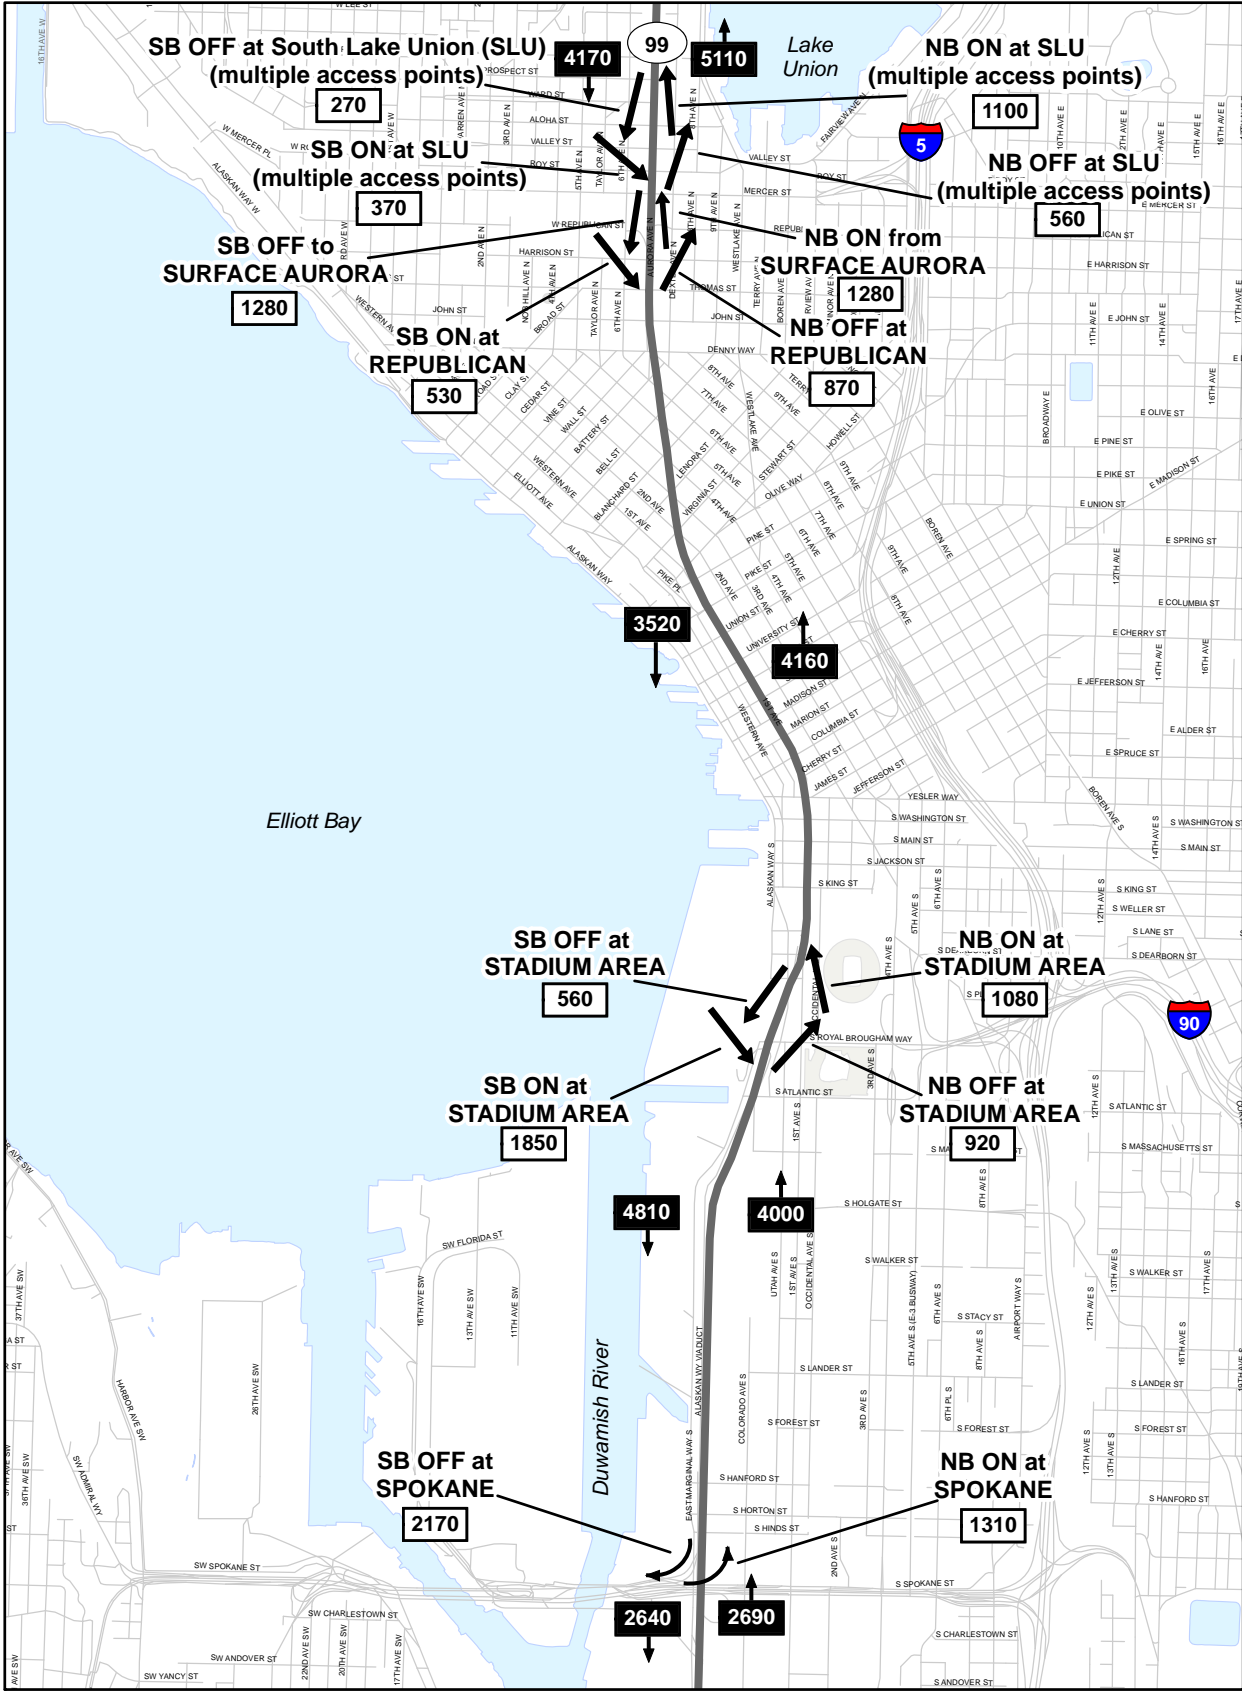

XXX Ramp Volumes

 2015 Project**

XXX Ramp Volumes
XXX SR 99 Mainline Volumes

**Exhibit 5-15
 PM Peak Hour Mainline
 and Ramp Volumes -
 2030 Project**

1 directionality, with 1,470 vehicles entering northbound SR 99 but only 1,180 vehicles
2 exiting southbound SR 99. South of downtown and the stadium area, mainline
3 volumes are noticeably higher in the southbound direction (5,040 vehicles) than in
4 the northbound direction (3,890 vehicles). At S. Spokane Street, volumes exiting
5 southbound to West Seattle (2,190 vehicles) are also higher than those entering
6 northbound from West Seattle (1,290 vehicles). As in the AM peak hour, the
7 volumes on the ramps at Seneca and Columbia Streets are lower than under existing
8 conditions because of the new ramps at S. King Street, which serve a similar
9 function.

10 At the north end of the study area, PM peak hour mainline volumes are higher in the
11 northbound direction (5,080 vehicles) than in the southbound direction (3860 vehicles),
12 as more vehicles are leaving the downtown area than are entering. Northbound on-
13 ramp volumes at Denny Way (1,460 vehicles) exceed those of the southbound off-ramp
14 (770 vehicles). In the Battery Street Tunnel, the volume of northbound vehicles (3,540
15 vehicles) again exceeds the volume of southbound vehicles (2,920 vehicles). The
16 ramps at the south end of the Battery Street Tunnel that provide access to and from the
17 north show directionality as well, with 560 vehicles entering northbound but only 200
18 vehicles exiting southbound. The Elliott/Western ramps to and from the south show
19 little directionality, with 1,390 vehicles entering southbound and 1210 vehicles exiting
20 northbound.

21 2015 Viaduct Closed (No Build Alternative)

22 As the viaduct is assumed to be closed in this scenario, no southbound traffic is
23 assumed to be on the facility between the Battery Street Tunnel off-ramp and the
24 S. King Street on-ramp. Similarly, no northbound traffic assumed to be on the
25 facility between the S. King Street off-ramp and the Battery Street Tunnel on-ramp.

26 2015 Project

27 As noted previously, in this scenario the stadium area ramps would provide the
28 connection to downtown from the south. The southbound stadium area on-ramp
29 is expected to have substantially higher volumes (1,850 vehicles) than the Baseline
30 conditions ramp at Columbia Street (1,000 vehicles) in the PM peak hour. This is
31 due to the fact that with the absence of the Elliott/Western ramps to the north,
32 some traffic traveling through the corridor to/from points northwest of the City
33 would use this ramp to connect from the alternative Alaskan Way surface route
34 through the waterfront area.

35 Likewise, volumes for the northbound stadium area off-ramp (900 vehicles) are also
36 expected to be higher than the Baseline ramp volume at Seneca Street (660 vehicles)
37 because it captures some of the traffic that previously would have used the Elliott
38 Avenue on-ramp. However, the mainline volume in both directions south of the

1 stadium area is anticipated to have lower volumes under 2015 Project conditions than
2 with the Baseline. PM peak hour mainline ramp volumes forecasted for the 2015
3 Project scenario are shown in Exhibit 5-14.

4 The bored tunnel would carry approximately 3,380 vehicles southbound and 3,910
5 vehicles northbound during the PM peak hour. This is lower than for Baseline
6 conditions, with 4,110 southbound and 4,190 vehicles northbound through midtown
7 between the Elliott/Western and Seneca/Columbia ramps. However, as described for
8 the AM peak hour, the bored tunnel would likely carry more traffic than the Battery
9 Street Tunnel under Baseline conditions, with 2,920 southbound and 3,540 northbound
10 vehicles during the PM peak hour. At the north end of the study area, mainline
11 volumes are anticipated to be similar to Baseline conditions. Entering and exiting
12 volumes from the South Lake Union area, including the ramps at Denny Way, are
13 expected to be slightly higher than under Baseline conditions.

14 2030 Project

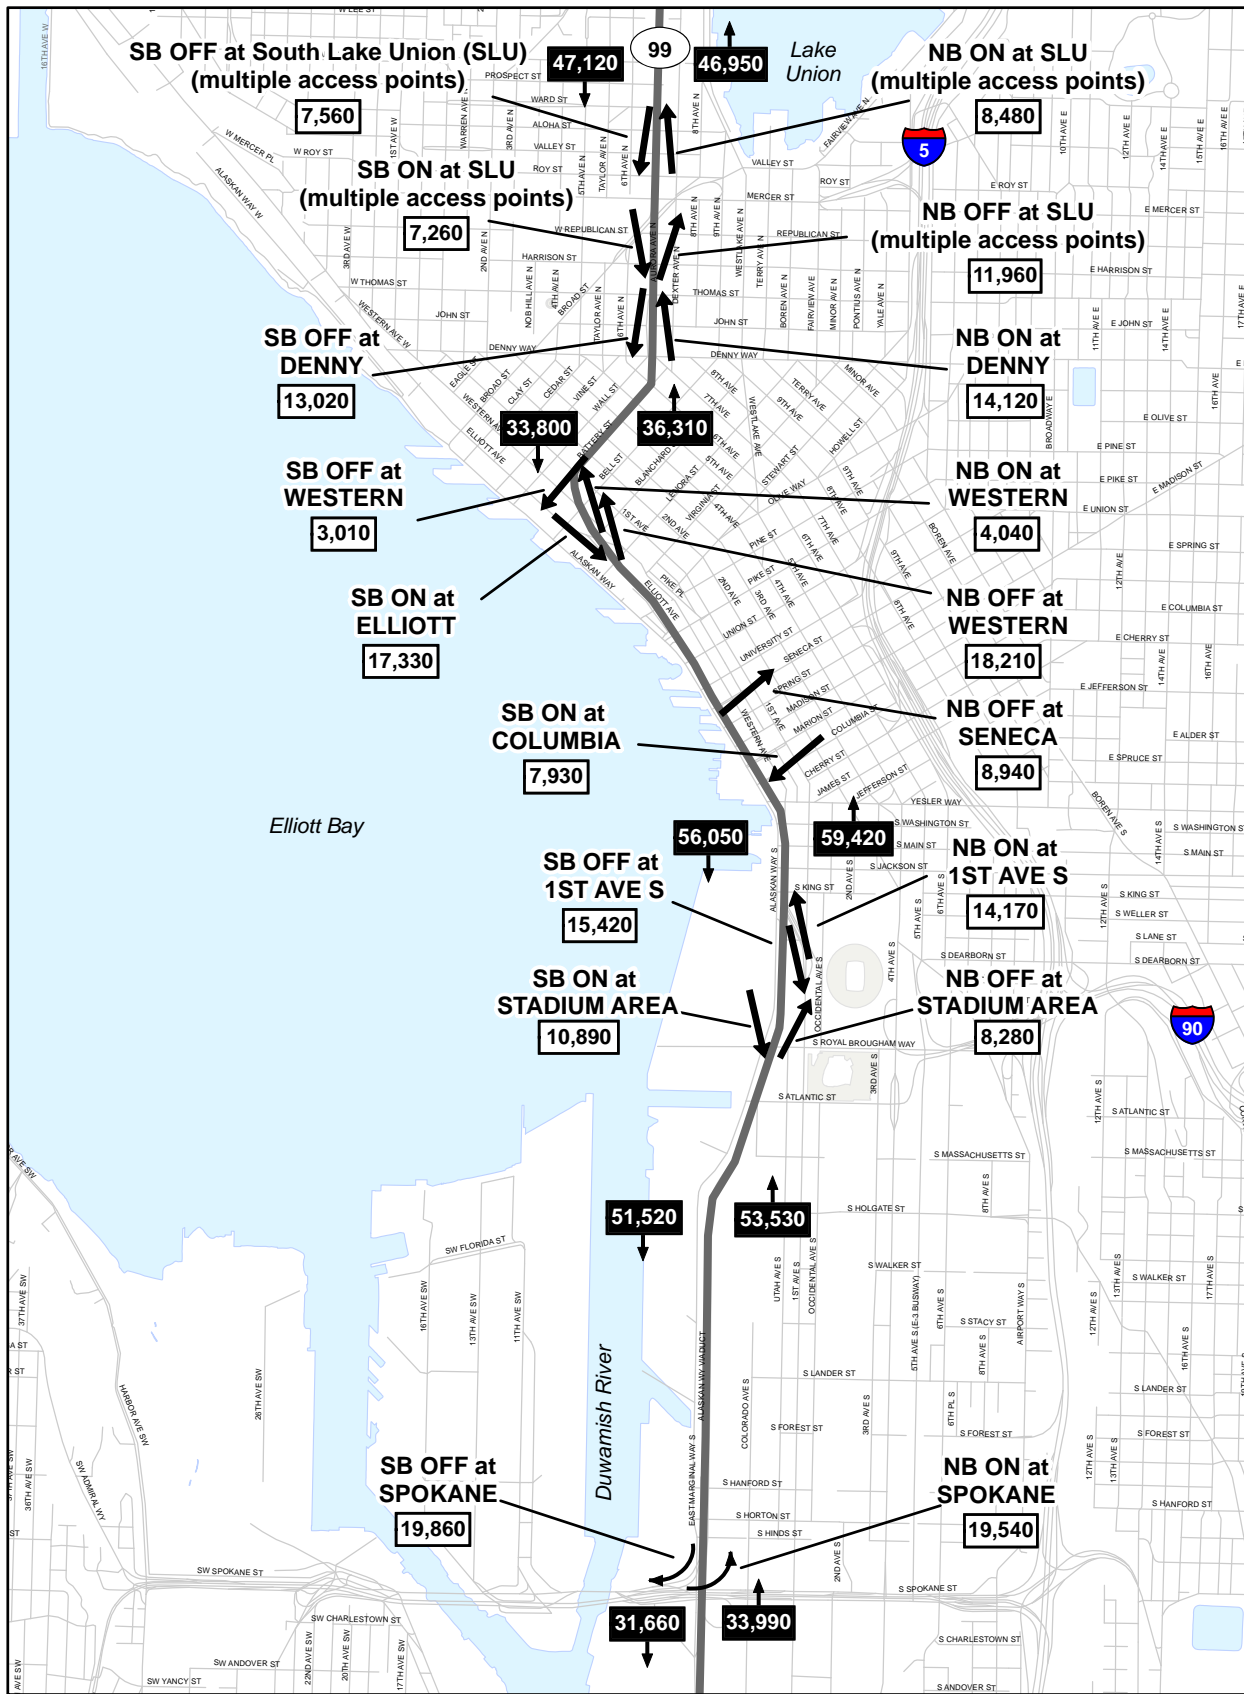

15 As was the case for the AM conditions, the 2030 Project volumes would be generally
16 similar to 2015 Project volumes, with only minor increases noted. PM peak hour
17 mainline ramp volumes forecasted for the 2030 Bored Tunnel Alternative are shown in
18 Exhibit 5-15.

19 **Daily**

20 Daily volumes for each of the scenarios are shown in Exhibits 5-16, 5-17, and 5-18.

21 2015 Baseline

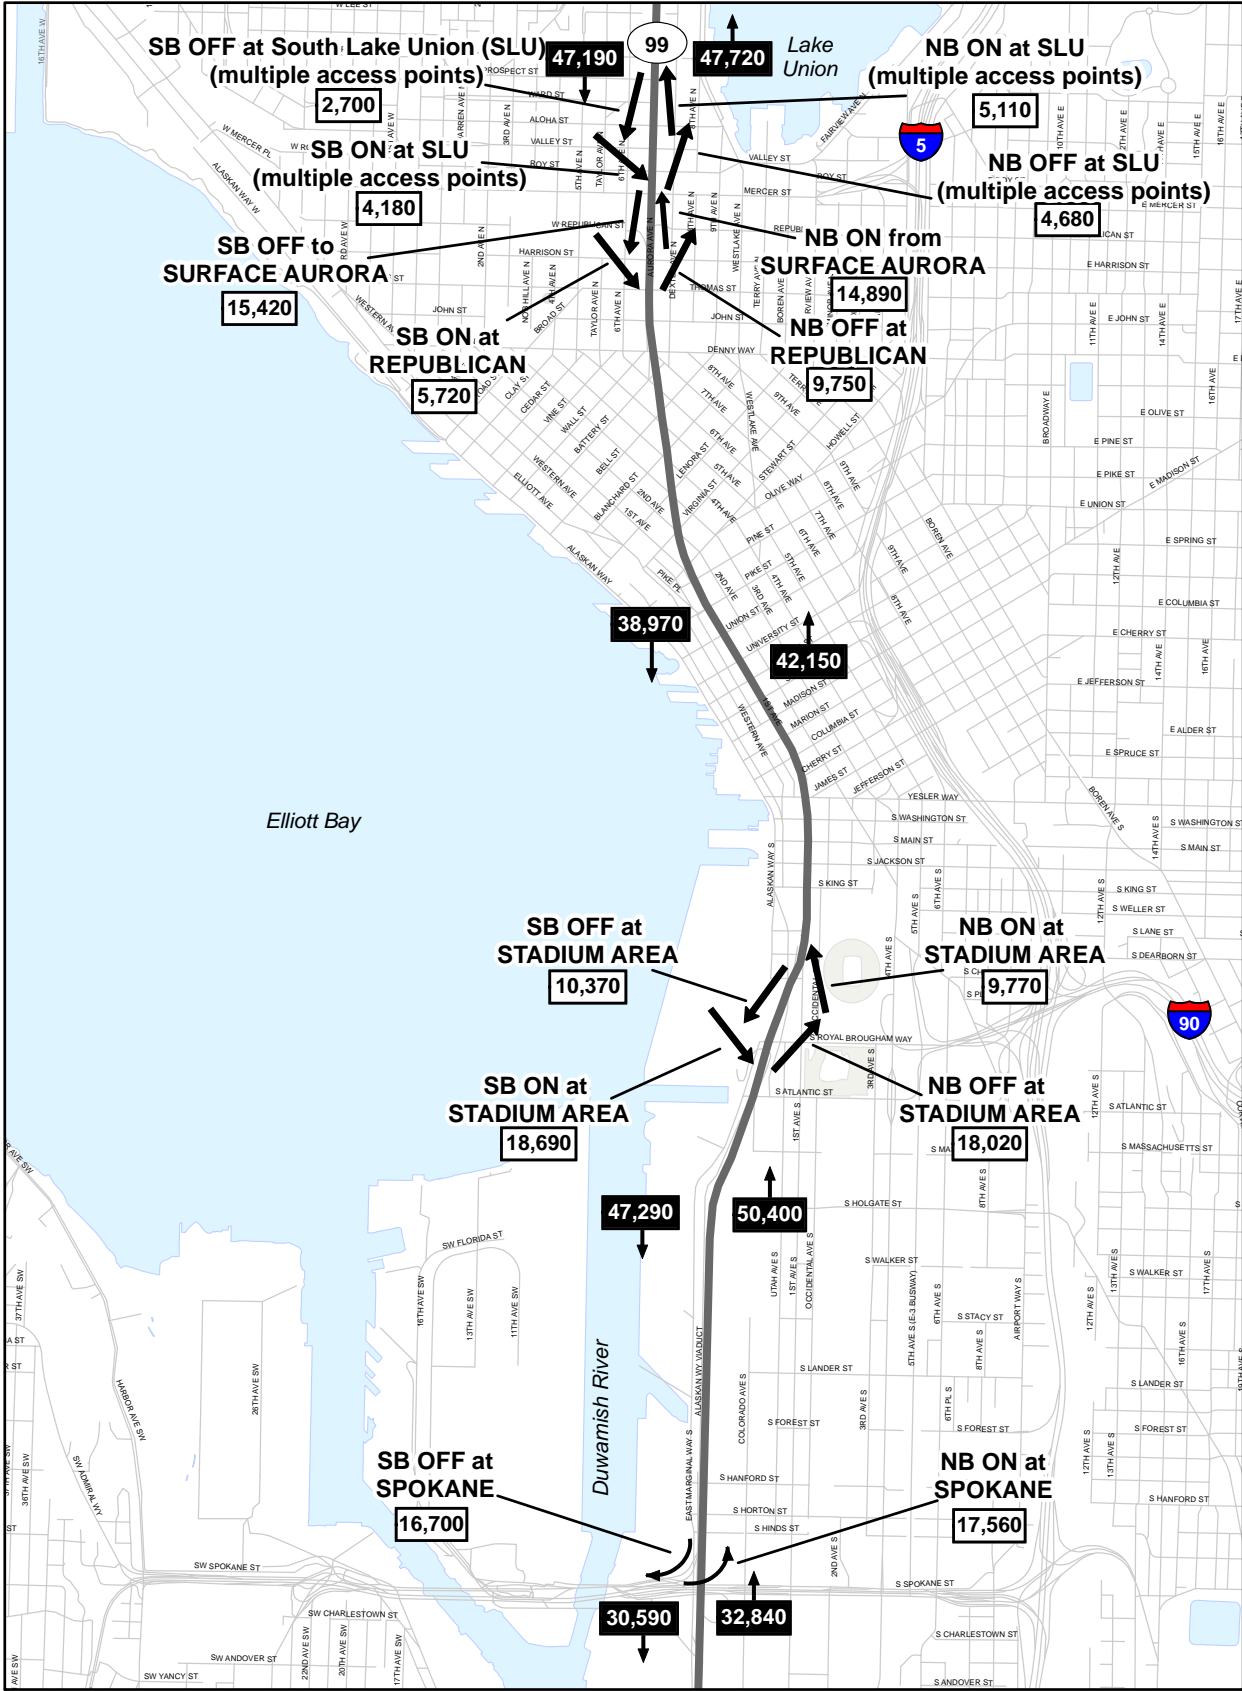

22 Similar to existing conditions, projected 2015 Baseline daily traffic volumes along
23 SR 99 are generally balanced by direction, with similar volumes leaving and entering
24 the central downtown area. At the north end of the study area, the majority of
25 southbound vehicles exiting from SR 99 exit at Denny Way (13,020), with a little more
26 than half that many (7,560) exiting at the multiple access points in South Lake Union.
27 Similarly, about 14,120 northbound vehicles enter SR 99 at Denny Way, with 8,480
28 entering at other South Lake Union access points. In the Battery Street Tunnel, the
29 volume of northbound vehicles (36,310 vehicles) is somewhat higher than the volume
30 of southbound vehicles (33,800 vehicles). Similar to existing conditions, the ramps at
31 the south end of the Battery Street Tunnel providing access to and from the north are
32 not as balanced as other ramps in the study area on a daily basis, with 4,040 vehicles
33 entering northbound but only 3,010 vehicles exiting southbound. However, the
34 Elliott/Western ramps to and from the south are relatively balanced, with 17,330
35 vehicles entering southbound and 18,210 vehicles exiting northbound.

XXX Ramp Volumes

XXX SR 99 Mainline Volumes

Note: Totals may not sum due to rounding.

**Exhibit 5-18
Daily Mainline
and Ramp Volumes -
2030 Project**

1 The downtown ramps providing access to and from the south are relatively balanced,
2 with 7,930 vehicles entering southbound at Columbia Street and 8,940 vehicles exiting
3 northbound at Seneca Street. The volumes on the First Avenue S. ramps are similarly
4 balanced, with 14,170 vehicles entering northbound and 15,420 vehicles exiting
5 southbound. The new ramps at S. King Street are somewhat unbalanced, with more
6 vehicles entering southbound (10,890) than exiting northbound (8,280). South of
7 downtown and the stadium area, mainline volumes are generally balanced by direction.
8 At S. Spokane Street, volumes exiting southbound to West Seattle (19,860) are similar to
9 those entering northbound from West Seattle (19,540). As in the AM and PM peak
10 hours, the volumes on the ramps at Seneca and Columbia Streets are lower than in the
11 Existing Conditions scenario because of the new ramps at S. King Street, which serve a
12 similar function. Daily mainline and ramp volumes are shown in Exhibit 5-16.

13 2015 Viaduct Closed (No Build Alternative)

14 As the viaduct is assumed to be closed in this scenario, no southbound traffic is
15 assumed to be on the facility between the Battery Street Tunnel off-ramp and the
16 S. King Street on-ramp. Similarly, no northbound traffic assumed to be on the
17 facility between the S. King Street off-ramp and the Battery Street Tunnel on-ramp.

18 2015 Project

19 As with the AM and PM peak hours, the southbound stadium area on-ramp is
20 expected to have substantially higher daily volumes (18,690 vehicles) than the
21 Baseline conditions ramp at Columbia Street (7,930 vehicles).

22 Likewise, volumes for the northbound stadium area off-ramp (18,020 vehicles) are also
23 expected to be higher than the Baseline ramp volumes at Seneca Street (8,940), again
24 because it captures some of the traffic that previously would have used the Elliott on-
25 ramp. Also, similar to AM and PM peak hour conditions, traffic volumes in both
26 directions south of the stadium area are anticipated to be lower under 2015 Project
27 conditions than the Baseline. Daily mainline ramp volumes forecasted for the 2015
28 Bored Tunnel Alternative are shown in Exhibit 5-17.

29 The bored tunnel would carry approximately 38,970 vehicles southbound and 42,150
30 vehicles northbound on a daily basis. This is lower than under Baseline conditions, with
31 56,050 southbound and 59,420 northbound vehicles through midtown between the
32 Elliott/Western and Seneca/Columbia ramps. However, as described for the AM and
33 PM peak hours, the bored tunnel would likely carry more daily traffic than the Battery
34 Street Tunnel under Baseline conditions, with 33,800 southbound and 36,310
35 northbound vehicles. In general, although SR 99 volumes through midtown are
36 projected to be lower than in the Baseline scenario, screenline analysis shows that
37 approximately the same number of trips would be accommodated by the overall system,
38 including I-5 and parallel arterials. At the north end of the study area, mainline volumes

1 are anticipated to be similar to those under Baseline conditions. Entering and exiting
 2 volumes from the South Lake Union area, including the ramps at Denny Way, are
 3 expected to be slightly higher than under Baseline conditions.

4 2030 Project

5 As was the case for the AM and PM peak hour conditions, the 2030 Project daily
 6 volumes would be generally similar to 2015 Project volumes, with only minor
 7 increases noted. Daily mainline ramp volumes forecasted for the 2030 Bored
 8 Tunnel Alternative are shown in Exhibit 5-18.

9 **5.2.2 SR 99 Mainline Level of Service**

10 This section describes the AM and PM peak hour level of service (LOS) for corridor
 11 segments under the 2015 Baseline and Project (Bored Tunnel Alternative) scenarios.
 12 While LOS provides a general gauge of how a facility performs overall, it is not
 13 considered a comprehensive measure for comparing scenarios for mainline
 14 conditions since ramp locations and segment arrangements may vary considerably
 15 among the scenarios. Additionally, as indicated in Chapter 2, because SR 99's posted
 16 speeds are less than a typical freeway's, the LOS (as based on the Transportation
 17 Research Board's Highway Capacity Manual [HCM] density ranges for freeways)
 18 would likely be lower than is truly experienced on the facility. Hence, the mainline
 19 LOS results are better suited for a relative comparison between scenarios as opposed
 20 to a true indication of operating levels. Projected speeds and travel times along the
 21 facility are better indicators of expected performance. SR 99 mainline LOS is
 22 summarized by segment for the Baseline, 2015 Project, and 2030 Project scenarios in
 23 Exhibits 5-19 to 5-22, reflecting both directions in the AM and PM peak hours.

2

3 **2015 Baseline LOS**

4 As shown in the exhibits above, the majority of the evaluated corridor is expected
 5 to operate at LOS E or LOS F conditions under 2015 Baseline conditions for the
 6 AM and PM peak hours.

7 The high levels of congestion identified under Baseline conditions are primarily
 8 due to merging and weaving friction associated with on-ramp and off-ramp areas
 9 within the SR 99 study segment, as well as geometric constraints such as narrow
 10 lanes and limited sight distance. Current traffic flow conditions in the downtown
 11 area show similarly high levels of congestion during peak commute periods. Key
 12 friction areas related to northbound ramp merging and weaving include the on-
 13 ramp from First Avenue S. in the south end, the Seneca off-ramp in mid-town,
 14 and the off-ramp to Western Avenue. The northbound on-ramp from Denny Way
 15 also causes some congestion north of the Battery Street Tunnel.

16 For the southbound direction, the off-ramp to Denny Way causes some spill back
 17 to the SR 99 mainline, while downstream friction from the Elliott Avenue on-
 18 ramp, Columbia Street on-ramp, and off-ramp to First Avenue S. also create
 19 pockets of congestion that affect peak period mainline flow. These merging and
 20 weaving areas are expected to collectively affect SR 99 corridor operations and are
 21 reflected in the level of service estimates shown in the exhibits above.

22 **2015 Viaduct Closed (No Build Alternative) LOS**

23 Traffic conditions in the corridor under the Viaduct Closed (No Build Alternative)
 24 scenario are anticipated to be highly congested compared with the 2015 Baseline.

1 These congested conditions are expected to result in extremely high travel times
2 for vehicles travelling through the CBD. For example, the travel time between
3 Woodland Park and S. Spokane Street in this scenario is estimated to be
4 approximately three times greater than the travel time under Baseline conditions.
5 LOS on SR 99 both north and south of the closed viaduct would likely be
6 degraded at the point where traffic starts to back up from the transition from
7 expressway to surface arterial system.

8 2015 Project LOS

9 The Bored Tunnel Alternative includes a number of changes to the SR 99 mainline
10 that are expected to affect traffic operations noticeably. Key highlights of these
11 changes include: (1) access consolidation in the South Lake Union area; (2) closure
12 of the Elliott/Western ramps, which would result in trips re-routing primarily to
13 Alaskan Way, with some to SR 99 via Mercer Street; and (3) relocation of
14 downtown access to the stadium area with ramps providing northbound on,
15 northbound off, southbound on, and southbound off movements to and from
16 SR 99.

17 The bored tunnel segment of the mainline project elements is projected to operate
18 at LOS D in the southbound direction and LOS E in the northbound direction for
19 both the AM and PM peak hours. This is improved over 2015 Baseline conditions
20 for SR 99 through midtown, which projects most segments to operate at LOS F in
21 both peak hours.

22 In the south end from approximately S. Spokane Street to the stadium off-ramp
23 area, northbound SR 99 speeds and densities would improve to LOS D levels
24 while mainline performance in the southbound direction would decline slightly
25 to LOS C in the AM peak hour. In the PM peak hour, LOS results are similar to
26 those shown for the 2015 Baseline scenario.

27 In the north end during the AM peak hour, southbound conditions are expected
28 to improve slightly over Baseline conditions to LOS E from LOS F in the Baseline
29 scenario. Northbound conditions would become slightly more congested at LOS
30 D. In the PM peak hour, the southbound speeds and densities would be in the
31 LOS E range, while northbound performance would be at LOS E to LOS F, similar
32 to Baseline conditions.

33 2030 Project LOS

34 Traffic demand for SR 99 is expected to increase by approximately 7 percent
35 between 2015 and 2030. This would have some impact on LOS. As with the 2015
36 Project scenario, the bored tunnel segment of the mainline Project elements is
37 projected to operate at LOS D in the southbound direction and LOS E in the
38 northbound direction in the AM peak hours. However, in the PM peak hour, due

1 to the increase in traffic demand, level of service is projected to decline from LOS
 2 D in 2015 to LOS E in 2030 in the southbound direction and from LOS E to LOS F
 3 in the northbound direction.

4 In the south end from approximately S. Spokane Street to the stadium off-ramp
 5 area, southbound SR 99 speeds and densities would remain at LOS C levels, while
 6 mainline performance in the northbound direction would decline from LOS D to
 7 LOS E in the AM peak hour. Similarly, in the PM peak hour, southbound SR 99
 8 operations would remain at LOS D, while mainline performance in the
 9 northbound direction would decline from LOS D to LOS F.

10 In the north end during the AM peak hour, southbound conditions are expected
 11 to decline from LOS E to LOS F, while northbound conditions would remain at
 12 LOS D. During the PM peak hour, level of service is expected to remain the same
 13 as those under 2015 Project conditions for both directions.

14 **5.2.3 SR 99 Mainline Speeds**

15 This section discusses the AM and PM peak hour travel speeds for corridor
 16 segments under the Baseline, 2015 Project, and 2030 Project scenarios. As with
 17 LOS, comparing travel speeds between scenarios can present certain challenges
 18 since the ramp and segment arrangements vary among the scenarios. The speeds
 19 are presented in tabular format in Exhibits 5-23 to 5-26. To assist in comparison,
 20 the results are presented side-by-side graphically in Exhibits 5-27 and 5-28.

2
3 Segment travel speed results confirm LOS findings, with congested conditions
4 causing slower speeds on the Baseline SR 99 through midtown. As indicated
5 previously, the Viaduct Closed (No Build Alternative) scenario is expected to
6 result in highly congested conditions, with corresponding speeds much lower
7 than those estimated under Baseline conditions. Speeds in the bored tunnel
8 would be approximately 44 to 46 miles per hour in both directions in both the AM
9 and PM peak hours in 2015, and between 40 and 46 miles per hour in 2030. This
10 compares with speeds ranging from 14 to 49 miles per hour for SR 99 in the
11 Baseline scenario, depending on segment and time period.

12 In the south end of the corridor from S. Spokane Street to the stadium off-ramp
13 area, in the 2015 Project scenario, speeds for northbound SR 99 would be slightly
14 higher compared to Baseline conditions, with speeds in the southbound direction
15 slightly lower in the AM peak hour. In the PM peak hour, speeds would be
16 similar between the Baseline and Project conditions in 2015. In 2030, speeds
17 would be similar to 2015 conditions in the southbound direction, but are
18 anticipated to degrade in the northbound direction, with speeds as low as 32
19 miles per hour during the PM peak hour due to slowdowns associated with the
20 friction caused by the northbound stadium on-ramp merge.

21 In the north end during the AM peak hour, southbound conditions in the 2015
22 Project scenario are expected to be slightly better, at 33 miles per hour, compared
23 to 28 miles per hour in the Baseline scenario. Northbound speeds would be
24 similar in both Baseline or Project scenarios. In the PM peak hour, speeds would
25 again be similar in these scenarios. Speeds for the north end in 2030 are
26 anticipated to be similar to those seen in 2015 for both AM and PM peak hours.

1 5.3 Traffic Operations at Key Arterial Intersections

2 To assess the impacts of each project scenario on other streets within the transportation
3 system, a description of intersection operations at selected locations is presented in
4 this section. Intersection performance is discussed and summarized for four
5 applicable scenarios: 2015 Baseline, 2015 Viaduct Closed (No Build Alternative), 2015
6 Project and 2030 Project. The primary performance measure used for this analysis is
7 Level of Service (LOS), which is a commonly used measure of operational effectiveness
8 for transportation facilities. LOS is used to assess a variety of transportation facilities
9 ranging from arterials to freeway segments. For the evaluation of signalized
10 intersections, LOS is specifically based on the *average vehicle delay* calculated for a given
11 intersection. LOS is represented by a letter grade ranging from “A” (low delays and
12 free flow traffic conditions) to “F” (very congested or break-down conditions).

13 The intersection analysis results are summarized by the following sub-areas:

- 14 • South
- 15 • Central
- 16 • North

17 The specific locations selected for analysis were based on several factors related to the
18 proximity of the intersection to the SR 99 corridor or its access points, forecasted traffic
19 volumes associated with the locations under the range of scenarios evaluated, and
20 current congestion levels. Only signalized intersections (existing or proposed) were
21 analyzed. All signalized intersections directly affected by, or created as a result of,
22 implementation of the Project are included in the analysis.

23 Intersections that are projected to operate at Levels of Service (LOS) E or F indicate
24 those locations that are most likely to experience substantial congestion during the
25 peak hour. Intersections that operate at LOS A-D would experience little to moderate
26 congestion levels during peak times and generally are not of concern. While traffic
27 congestion is a common occurrence in the urban environment, identifying LOS E and
28 F intersections does indicate those areas that warrant consideration of how congestion
29 may affect major travel movements and specific travel modes such as transit or freight.
30 Also of concern is whether congestion may lead to air quality concerns, which is
31 assessed in the Air Discipline Report (Appendix M of the SDEIS).

32 Key Findings

- 33 • While most intersections in the south end are expected to operate at LOS
34 D or better conditions under the 2015 Baseline, five locations are expected
35 to operate at LOS E or F conditions during one or both of the peak hours.
36 The project in general would maintain or modestly improve intersection
37 traffic operations in the area for the 2015 timeframe. All intersections are

- 1 expected to operate at LOS D or better during the AM peak hour, while
2 three intersections are forecasted to operate at LOS E or F during the PM
3 peak. By 2030, growth in traffic is expected to result in one LOS E
4 intersection during the AM peak and three LOS F intersections during the
5 PM peak.
- 6 • All intersections evaluated in the central sub-area are expected to operate
7 at LOS D or better during the AM peak; only First Avenue at Columbia
8 Street would experience LOS F conditions during the PM peak. Results
9 are similar for the 2015 Project scenario, which would reduce congestion
10 on many downtown streets (including the aforementioned First Avenue
11 intersection at Columbia Street), but would increase congestion at the
12 Western Avenue at Broad Street intersection (LOS E during the PM peak)
13 due to increased traffic turning from Broad Street onto Western Avenue.
14 Note that the improvements proposed as part of the Program, described
15 under Cumulative Effects, would improve the LOS at this location. By
16 2030, traffic growth is expected to result in one LOS E intersection during
17 the AM peak, and to worsen conditions at the Broad Street and Western
18 Avenue intersection to LOS F.
 - 19 • In the north end sub-area, LOS E and F conditions are expected at four
20 intersections during the AM peak and at six locations during the PM peak,
21 including both directions of Aurora Avenue (Denny ramps) at Denny
22 Way. The 2015 Project would create a number of new intersections, all of
23 which are expected to operate well. Elsewhere, four LOS E intersections
24 are expected during the AM peak, while nine locations are expected to
25 operate at LOS E or F conditions during the PM peak. Many of these
26 locations are along Mercer Street, which carries a substantial share of the
27 east-west traffic in the area and experiences very congested conditions
28 during the peak periods today and under 2015 Baseline conditions as well.
29 By 2030, traffic growth is expected to result in 7 intersections operating at
30 LOS E or F conditions during the AM peak, and 12 during the PM peak.
 - 31 • Though not specifically analyzed for intersection operations, the Viaduct
32 Closed (No Build Alternative) scenario would considerably increase the
33 number of intersections operating at LOS E and F, and would likely
34 increase delay at many of these locations well beyond the LOS F
35 threshold, leading to substantial congestion. This is especially likely for
36 intersections in the north and south sub-areas and along north-south
37 arterials through the central waterfront and downtown as traffic shifts
38 from the SR 99 corridor to alternate surface street routes.

1 Detailed intersection analysis results are shown in Exhibits 5-29, 5-30, and 5-31 for
2 the south, central, and north, respectively. Exhibit 5-32 reports results for
3 intersections that would be affected differently by Option 2.

4 5.3.1 South Sub-Area

5 Detailed intersection analysis results for the south sub-area, which consists of
6 arterials and intersections south of S. King Street and west of Fourth Avenue, are
7 shown in Exhibit 5-30. Intersection performance for the study locations was
8 evaluated using Synchro and VISSIM traffic analysis software.

9 2015 Baseline

10 The S. Holgate Street to S. King Street Viaduct Replacement Project improvements
11 to SR 99 will be in place by 2015 and are considered part of the Baseline
12 conditions. That project includes revisions to the street system west of First
13 Avenue S. near S. Atlantic Street and S. Royal Brougham Way. Additionally, new
14 ramp connections to SR 99 will be provided at S. King Street/Alaskan Way S.
15 These ramps will provide an entrance to southbound SR 99 and an exit from
16 northbound SR 99, complementing the existing Columbia and Seneca ramps and
17 providing additional access into the central waterfront and stadium areas. These
18 new ramps are expected to draw additional traffic onto some area roadways,
19 notably Alaskan Way S. Intersections on Alaskan Way are generally expected to
20 operate to LOS D or better conditions in the south end sub-area, however. One
21 exception is a new intersection on Alaskan Way S. where traffic exits the holding
22 area for ferry traffic; this intersection is expected to operate at LOS F during both
23 the AM and PM peaks, though this is largely a result of the operational approach
24 to hold ferry traffic for a period of time and release it in platoons. Traffic on
25 Alaskan Way would not experience particularly long delays at this location.

26 The intersection of E. Marginal Way/T-46 at S. Atlantic Street is projected to
27 operate at a LOS E during both the AM and PM peak hours, which reflects the
28 need for a relatively long cycle length in order to accommodate all movements
29 when the U-shaped undercrossing is in operation. In addition, the signal system
30 for this location must also provide for movements at the adjacent Colorado
31 Avenue S./S. Atlantic intersection, further adding to potential delays in the
32 general area. The signal system also serves rail crossings on the BNSF tail track
33 while diverting traffic to the new undercrossing. As a result, even under
34 moderately congested conditions, travelers would face delays at this location as
35 the traffic signal cycles through all necessary signal phases.

Dexter Avenue N.	Mercer Street	n/a	n/a	n/a	n/a					n/a	n/a	n/a	n/a				

1 The high volume intersection of First Avenue S. at S. Atlantic Street is expected to
2 operate at LOS E conditions for both the AM and PM peak hours. During the AM
3 peak hour, heavy westbound left-turn movements queuing back into the
4 westbound through travel lanes are problematic. During the PM peak hour,
5 congestion levels are impacted by heavy northbound through movements and
6 southbound left-turns, which require considerable portions of the available signal
7 cycle lengths to accommodate.

8 First Avenue S. at S. Royal Brougham Way is expected to improve from LOS E
9 (AM) today to LOS C under 2015 Baseline conditions due to improvements to
10 SR 519 and those associated with the S. Holgate Street to S. King Street Viaduct
11 Replacement Project.

12 The heavily traveled intersection of S. Royal Brougham Way at Fourth Avenue S.
13 is expected to operate at LOS E during the PM peak hour. It should be noted that
14 this intersection also currently operates with heavy congestion (LOS E
15 conditions).

16 The intersection of First Avenue S. at Yesler Way also is expected to operate at
17 LOS E during PM peak hour. Delays at this location are primarily due to
18 increased traffic volumes on First Avenue S. compared to pre-Baseline (no
19 S. Holgate Street to S. King Street Viaduct Replacement Project) conditions.

20 **2015 Viaduct Closed (No Build Alternative)**

21 As discussed previously in the Viaduct Closed (No Build Alternative) scenario,
22 SR 99 mainline traffic in the south end would transition from the S. Holgate Street
23 to S. King Street structure to/from the Alaskan Way surface arterial via a set of
24 single lane ramps connecting to Alaskan Way at S. King Street. Consequently,
25 traffic capacity into and out of the downtown area on SR 99 is expected to be
26 severely constrained, with noticeable backups occurring at intersections within
27 and near this transition point.

28 Though not specifically assessed for intersection operations, inferences based on
29 modeled changes in travel patterns may be drawn. Locations in the south end
30 most likely to experience considerable congestion are the transition ramps from
31 SR 99 to Alaskan Way/East Frontage Road/S. King Street, as well as the
32 intersections along First Avenue S. at S. Atlantic Street and at S. Royal Brougham
33 Way, along Alaskan Way north of S. King Street, and most intersections on First
34 Avenue between S. King Street and Madison Street. These locations are expected
35 to operate with substantial levels of congestion due to the large increases in traffic
36 volumes diverted from the SR 99 corridor.

1 **2015 Project**

2 Under the 2015 Project scenario, traffic patterns in the south end would change
3 substantially from the Baseline scenario due to the relocation of the SR 99 stadium
4 ramps and the introduction of newly created intersections within the study
5 network. The First Avenue S./Railroad Way ramps would be removed and
6 replaced with ramps that connect to a new E. Frontage Road at S. Royal
7 Brougham Way (and continuing on to S. Atlantic Street as well). This ramp
8 relocation would redistribute traffic to Royal Brougham Way and S. Atlantic
9 Street west of First Avenue S., rather than to First Avenue S. between Atlantic
10 Street and Railroad Way. Additionally, Alaskan Way S. would no longer connect
11 directly through to E. Marginal Way and S. Atlantic Street, which would shift
12 some trips from the central waterfront First Avenue S. via three new east/west
13 roadways and associated intersections.

14 Under the 2015 Project scenario, the intersection of First Avenue S. at S. Atlantic
15 Street is anticipated to improve to LOS C during the AM peak but remain at LOS
16 E during the PM peak, due in part to the heavy traffic on the west leg of S.
17 Atlantic Street traveling from the relocated SR 99 ramps.

18 The new intersections along Alaskan Way and First Avenue S. created by the
19 project are all projected to operate at LOS A or B.

20 First Avenue S. at Yesler Way is expected to operate at LOS F during the PM peak
21 hour due to increased traffic volumes on First Avenue S. over 2015 Baseline
22 conditions. Note that this assumes that First Avenue S. would remain as one lane
23 each direction with a parking lane in both directions. If parking were prohibited
24 during the PM peak period, then operations would improve at this location.

25 The intersection of S. Royal Brougham Way at Fourth Avenue S. would continue
26 to show high levels of congestion, with delays in the LOS E range during PM
27 peak hour.

28 **2030 Project**

29 As shown in Exhibit 5-29, intersection operations under 2030 Project conditions
30 closely mirror those under the 2015 Project scenario. Of the 22 signalized
31 intersections investigated for the south end, traffic growth between 2015 and 2030
32 is forecast to degrade LOS at five locations by one grade, though three of these are
33 LOS C or better, indicating very little congestion.

34 Specific locations where LOS would degrade during the AM peak hour include
35 E. Marginal Way (T-46 Driveway)/S. Atlantic Street, First Avenue S./S. Atlantic
36 Street, First Avenue S./Dearborn Street, and Fourth Avenue S./S. Royal Brougham
37 Way. The primary factors influencing future changes in LOS at these locations

1 between 2015 and 2030 are mainly related to general background growth in traffic
2 volumes due to changes in local and/or regional land use intensity.

3 During the PM peak hour, an estimated 5 of the 22 total intersections evaluated
4 are expected to show an increase in congestion levels based on the LOS results.
5 These intersections include two crossings of E. Frontage Road at S. Atlantic Street
6 and S. Royal Brougham Way, as well as First Avenue S. at Charles Street, First
7 Avenue S. at S. Atlantic Street, and Fourth Avenue S. at Royal Brougham Way.
8 Of these locations, only the latter two locations would experience higher levels of
9 congestion at LOS E or LOS F.

10 5.3.2 Central Sub-Area

11 Detailed intersection analysis results for the central sub-area are shown in
12 Exhibit 5-30. As with the south end intersections, traffic operations for the
13 targeted locations were analyzed using both Synchro and VISSIM traffic analysis
14 software.

15 2015 Baseline

16 Under the 2015 Baseline scenario, two intersections during the PM peak hour are
17 forecasted to operate at LOS E or F. No intersections are forecasted to operate
18 under such conditions during the AM peak hour. However, for the AM peak
19 hour the intersection of First Avenue at Seneca Street is anticipated to experience
20 substantial queuing.

21 Since traffic in the downtown during the AM and PM peak hours is expected to
22 grow only modestly, intersection signal phasing patterns were generally carried
23 over from existing conditions. However, intersection signal timing splits (green
24 time durations) and offsets were optimized.

25 Under the 2015 Baseline scenario, the intersections of First Avenue at Columbia
26 Street and Elliot Avenue at Wall Street were identified as congested locations,
27 with delays at LOS E or worse during the PM peak hour.

28 The intersection of First Avenue at Columbia Street serves as the access point to
29 southbound SR 99 from downtown, and therefore serves relatively high
30 concentrations of traffic. Queues from the Columbia Street southbound on-ramp
31 frequently spill back to First Avenue, causing additional delays at this
32 intersection.

33 The intersection of Elliott Avenue at Wall Street is forecasted to operate at
34 capacity during the PM peak hour, with delays in the LOS E range. Background
35 traffic growth due to increased land use intensity in the Belltown area between
36 existing conditions and 2015 Baseline conditions is the primary factor leading to
37 increased delay at this intersection.

1 Under the 2015 Baseline scenario, a number of intersections are anticipated to
2 operate at acceptable levels of service but with queues expected to spill back and
3 affect SR 99 mainline traffic. Traffic on the northbound SR 99 off-ramp to Seneca
4 Street is anticipated to spill-back from the intersection of Seneca Street at First
5 Avenue onto SR 99, causing delays along SR 99. Also, the intersection of Western
6 Avenue at Battery Street is expected to experience queues that spill back onto
7 both the southbound SR 99 Battery Street off-ramp and northbound Western
8 Avenue off-ramp, resulting in some queues and delay on SR 99.

9 2015 Viaduct Closed (No Build Alternative)

10 Traffic delays and congestion levels for intersections within the central sub-area
11 under the 2015 Viaduct Closed (No Build Alternative) scenario are expected to be
12 higher for the majority of locations than under 2015 Baseline conditions. Key
13 groupings of intersections that would likely experience the most pronounced
14 increases in congestion would include the signalized intersections along Alaskan
15 Way (surface arterial), intersections on First Avenue, and those along the one-way
16 system of Second and Fourth Avenues.

17 While the geometric constraints upstream and downstream of the central
18 waterfront area would effectively meter traffic volumes into the downtown core,
19 the redistribution of SR 99 traffic to surface arterials would result in utilization of
20 available capacity on these downtown streets. As such, high levels of congestion
21 would be expected for key north-south arterials, as well as for east-west
22 connectors to/from I-5 between Union Street and James Street.

23 2015 Project

24 Under the 2015 Project scenario, the removal and/or relocation of some SR 99 on-
25 and off-ramps is expected to result in changes in travel patterns to and from
26 SR 99. Ramps currently provided at Columbia Street, Seneca Street, Western
27 Avenue, and Elliott Avenue would be replaced by ramps to Alaskan Way in the
28 stadium area, as well as by improved connections in the South Lake Union area.
29 Traffic that uses the Columbia and Seneca Street ramps today would instead
30 enter/exit on Alaskan Way at Plummer Street and continue into the Central
31 Business District. Elliott/Western trips could similarly use Alaskan Way to travel
32 to Broad Street, or instead continue through the new bored tunnel and enter/exit
33 in the South Lake Union area.

34 Under the 2015 Project scenario, the intersection of Western Avenue at Broad
35 Street is anticipated to operate with heavy congestion during the PM peak hour.
36 The increase in delay and congestion at this intersection is due to an expected
37 increase in conflicts between southbound left-turning vehicles and northbound
38 through traffic. However, the rest of the intersection approaches are anticipated

1 to operate with low levels of congestion. Note that the improvements proposed
2 as part of the Program, described in Chapter 7, Cumulative Effects, would
3 improve the LOS at this location.

4 Traffic operations would improve on most streets within the central business
5 district, particularly at Columbia Street and First Avenue, which is congested
6 today by SR 99 ramp traffic.

7 **2030 Project**

8 Under 2030 Project conditions, the majority of intersections are anticipated to
9 operate much as they do under 2015 Project conditions in the central sub-area.
10 During the AM peak hour the intersection of Second Avenue at Marion Street is
11 anticipated to operate under constrained conditions (at or below LOS E). The
12 increased delay would generally be due to projected traffic growth between 2015
13 and 2030 and greater use of Second Avenue as a southbound route through the
14 city.

15 The intersection of Western Avenue at Broad Street is anticipated to experience
16 heavy congestion during the PM peak hour 2030 Project scenario. Again, the
17 expected increase in delay and congestion at this intersection between 2015 and
18 2030 is likely due to projected traffic growth. All approaches for this location,
19 with the exception of the northbound Western Avenue approach, are expected to
20 operate under constrained conditions (at or below LOS E).

21 **5.3.3 North Sub-Area**

22 Two configurations for Sixth Avenue and the southbound on-ramp are being
23 considered. Option 1 proposes to build a new roadway that would extend Sixth
24 Avenue N. from Harrison to Mercer Streets in a typical grid formation. The new
25 roadway would have two lanes in each direction with signalized intersections at
26 Republican and Mercer Streets. Option 2 proposes to build a new roadway that
27 would extend Sixth Avenue N. in a curved formation between Harrison and
28 Mercer Streets. The new roadway would have two lanes in each direction and a
29 signalized intersection at Republican Street. The two options are shown in
30 Exhibit 5-33. Intersection analysis results for the north end sub-area, which
31 consists of arterials and intersections south and west of Lake Union and near
32 Seattle Center, are shown in Exhibit 5-31. Operational results for intersections
33 affected by the Option 2 configuration are shown in Exhibit 5-32.

Option 1

Option 2

Exhibit 5-33
North Portal Options

1 **2015 Baseline**

2 Under the 2015 Baseline scenario in the north area, it is assumed that the Mercer
3 Corridor East project would convert the segment of Mercer Street from Fairview
4 Avenue to Dexter Avenue N. into a two-way facility by widening this segment
5 from four lanes (currently one-way eastbound) to three lanes in each direction.
6 As part of these sub-area improvements, Valley Street would be reduced to a two-
7 lane roadway (one lane each direction). The conversion to a two-way roadway
8 would also necessitate a new signalized intersection on Mercer Street to provide
9 access to Broad Street.

10 Two intersections during the AM peak hour and four intersections during the PM
11 peak hour are expected to operate at LOS E or worse in the 2015 Baseline scenario.
12 The intersections of Valley Street at Fairview Avenue N., and Mercer Place at Roy
13 are also expected to operate at LOS E or worse during the AM peak hour. The
14 intersections of Mercer Street at Fairview Avenue N., Mercer Street at Westlake
15 Avenue N., Denny Way at Aurora, Western Avenue W. at Elliott Avenue W., and
16 Mercer Place at Elliott Avenue are similarly expected to operate at LOS E or
17 worse during the PM peak hour. Note that even though the Mercer
18 Street/Fairview Avenue intersection is at LOS F, its delay is expected to be
19 substantially lower in the 2015 Baseline scenario than under existing conditions.

20 Analysis results for the AM peak hour show long queues at the intersection of
21 Valley Street at Fairview Avenue N. that could potentially spill back into the
22 adjacent intersections of Valley at Boren Avenue and Mercer Street at Fairview
23 Avenue N. The intersection of Mercer Place at Elliott Avenue is anticipated to
24 operate at a LOS F during the AM peak hour. Delays at this location are likely the
25 result of heavy projected volumes in the northbound direction and substantial
26 southbound traffic volumes turning left from Elliott Avenue to Mercer Place.
27 Substantial queues and delays are expected for this critical intersection.

28 As with existing conditions, the intersection of Mercer Street at Fairview
29 Avenue N. is expected to experience considerable delays and queuing for all
30 approaches during the PM peak hour. This is primarily due to the heavy volumes
31 to/from the I-5 ramps. The intersection of Mercer Street at Westlake Avenue N. is
32 anticipated to operate with high delays for all approaches. Long queues are
33 projected along north-south Westlake Avenue N. Long queues and high delays
34 are also expected at the intersection of Denny Way and the SR 99 ramps. This is
35 due to the heavy volumes entering and exiting SR 99, as well as heavy volumes
36 along Denny Way. The queues on the southbound off-ramp are not anticipated to
37 spill back onto SR 99. The intersection of Mercer Place at Elliott Avenue is
38 anticipated to operate at a LOS F during the PM peak hour.

1 **2015 Viaduct Closed (No Build Alternative)**

2 North end congestion levels under the 2015 Viaduct Closed (No Build
3 Alternative) scenario are generally expected to be higher than 2015 Baseline
4 conditions for the majority of locations. While the Battery Street Tunnel would
5 remain open in the Viaduct Closed (No Build Alternative), the SR 99 corridor
6 would terminate at the Battery Street/Western Avenue ramps. Traffic volume
7 estimates for this scenario show that the majority of traffic southbound on SR 99
8 would utilize the Broad Street and Denny Way off-ramps rather than the Battery
9 Street off-ramp. Similarly, in the northbound direction, most trips destined to the
10 north would likely use the Denny Way on-ramp rather than the upstream on-
11 ramp at the south end of the Battery Street Tunnel. As a result, key intersections
12 on Broad Street and Wall Street (southbound SR 99 traffic) and on Battery Street
13 (northbound SR 99 traffic) would be impacted noticeably. Heavy queuing and
14 long backups may be particularly severe at SR 99 ramp termini intersections such
15 as at Denny Way.

16 **2015 Project**

17 Under the 2015 Project scenario in the north area, several network changes are
18 expected for the SR 99 interchange area and surface streets south of Mercer Street.
19 East-west arterials such as John, Thomas, and Harrison Streets would all intersect
20 with a new north-south arterial (Aurora Avenue) with east-west through
21 movements allowed. The northbound SR 99 off-ramp south of Mercer Street and
22 the southbound on-ramp would both be located at Republican Street. Additional
23 surface street changes include the closure of Broad Street, extending Sixth Avenue
24 N. to Mercer Street, and converting Sixth Avenue N. from one-way to two-way
25 between Denny Way and Battery Street.

26 For the 2015 Project scenario, four intersections during the AM peak hour and
27 nine intersections during the PM peak hour are expected to operate with delays at
28 LOS E or worse. The intersections of Valley Street at Fairview Avenue N., Mercer
29 Place at Elliott Avenue, Dexter Avenue at Mercer Street, and Fairview Avenue at
30 Mercer Street are expected to operate at LOS E or worse specifically during the
31 AM peak hour.

32 During the AM peak hour, the intersection of Valley Street at Fairview Avenue N.
33 is projected to operate similarly to the 2015 Baseline scenario and to experience
34 queues that could potentially spill back into the adjacent intersections of Valley at
35 Boren Avenue N. and Mercer Street at Fairview Avenue N. The intersection of
36 Mercer Place at Elliott Avenue is anticipated to operate at LOS E during the AM
37 peak hour. Delays at this location are due to a heavy northbound through
38 movement that conflicts with the southbound left-turn movement. In addition,
39 queuing and delays along the north-south streets intersecting with Mercer Street

1 are anticipated, and therefore the intersections of Dexter Avenue at Mercer Street
2 and Fairview Avenue at Mercer Street are expected to operate at LOS E or worse.

3 During the PM peak hour, the intersection of Mercer Street at Fairview Avenue N.
4 is expected to experience high delays and queuing along all approaches. This is
5 mainly due to the heavy volumes to and from the I-5 ramps. Analysis results
6 indicate that this intersection operates with high delays under 2015 Baseline and
7 existing conditions. The intersection of Mercer Street at Westlake Avenue N. is
8 expected to operate with high delays for all approaches. Long queues are
9 projected on the north-south Westlake Avenue N. approaches in particular,
10 similar to 2015 Baseline conditions. The intersection of Mercer Place at Elliott
11 Avenue is anticipated to operate at a LOS F during the PM peak hour. Similar to
12 the AM peak hour delay, this delay is primarily due to a heavy northbound
13 through movement that conflicts with a heavy southbound left-turn movement.
14 The intersection of Sixth Avenue at Battery Street is anticipated to operate under
15 congested conditions due to Sixth Avenue becoming two-way. Analysis results
16 also show that queuing and delays along the north-south streets intersecting with
17 Mercer Street are anticipated.

18 An alternative north end configuration, known as Option 2, would include a
19 modified Sixth Avenue N. alignment near Republican Street and the on-ramp to
20 southbound SR 99. This option would align Sixth Avenue N. farther to the east
21 between Republican Street and Mercer Street, as shown in Exhibit 5-33. For this
22 analysis, it is assumed that the resulting intersection at Mercer Street would be
23 unsignalized and restricted to right turns for the northbound outbound approach
24 and right turns for the eastbound inbound movement. No westbound or
25 northbound left turns would be allowed.

26 The City of Seattle is currently assessing the feasibility and safety implications of
27 signaling this intersection in Option 2 to allow for all movements. However,
28 with the current assumption of no signal, a rerouting of trips accessing the
29 southbound on-ramp to SR 99 at Republican Street and other points along Sixth
30 Avenue from westbound SR 99 would be needed. Proposed access routes to the
31 southbound Republican Street on-ramp would be via Harrison Street and Thomas
32 Street from southbound Dexter Avenue, or alternatively, access southbound SR 99
33 via Mercer, Taylor, and Roy Streets.

34 Traffic operations for Option 2, in terms of delays and LOS, would not be
35 substantially different from the original concept for Sixth Avenue N. The Sixth
36 Avenue N. realignment would change the LOS at the Mercer Street/Dexter
37 Avenue N. intersection in the 2015 Project scenario because of an increase in the
38 westbound left-turn movement. The westbound left-turn volume would increase
39 by 170 vehicles per hour in the AM peak hour and by 150 vehicles per hour in the

1 PM peak hour, because the volume that would have turned left at Sixth Avenue
2 N. can no longer complete that turn. This volume was destined for either the
3 southbound SR 99 on-ramp at Republican Street or the street grid south of the
4 Republican Street on-ramp.

5 Some of the westbound left-turn volume at Sixth Avenue N. is expected to reroute
6 to the Roy Street connection to southbound SR 99; however, before any traffic
7 shifts there, the Roy Street approach already is projected to operate at LOS F and
8 at 15 percent over capacity in the PM peak hour and at LOS E with 47 seconds of
9 delay in the AM peak hour, which would offer a less desirable connection to
10 SR 99 than the Republican Street on-ramp.

11 With the additional volume at Mercer Street/Dexter Avenue N., the LOS changes
12 one grade from the 2015 Project (without Realignment) scenario in both peak
13 hours (LOS D to LOS E in the AM peak hour and LOS E to LOS F in the PM peak
14 hour). In the AM peak hour, some signal timing optimizations may slightly
15 improve delays; however, in the PM peak hour the intersection does not have
16 enough capacity to allow this movement more time without affecting other over-
17 capacity movements.

18 2030 Project

19 Under the 2030 Project scenario most intersections are anticipated to operate
20 much as they would in the 2015 Project scenario for the north area, with slight
21 increases in delays due to projected traffic growth. During the AM peak, similar
22 intersections are anticipated to operate under congested conditions as were
23 expected in the 2015 Project scenario. Additionally, the two intersections of
24 Dexter Avenue at Denny Way and Dexter Avenue at Aloha Street are also
25 expected to operate at LOS E or F. The increased delays at these intersections are
26 primarily due to the projected increase in traffic along Dexter Avenue by the 2030
27 horizon.

28 During the PM peak hour for the 2030 Project scenario, three additional
29 intersections are expected to operate at LOS E or F, beyond those anticipated in
30 the 2015 Project scenario. These include the intersections of Denny Way at
31 Aurora Avenue, Dexter Avenue at Denny Way, and Ninth Avenue at Mercer
32 Street. The intersection of Denny Way at Aurora Avenue/Battery Street/Wall
33 Street is anticipated to operate at a LOS E during the PM peak hour, which can be
34 attributed to traffic growth both on Denny Way and Aurora Avenue. In addition,
35 the adjacent intersection of Dexter Avenue at Denny Way is anticipated to operate
36 with increased delay by the 2030 horizon. Expected queuing activity between
37 these two closely spaced intersections would likely cause spillback to adjacent
38 intersections along Denny Way, resulting in additional delays on Denny Way.
39 The intersection of Ninth Avenue at Mercer Street is anticipated to fall from LOS

1 D in 2015 to LOS F in 2030 due to increases in traffic for all approaches. The
2 majority of additional queues and delays at this location are expected for the
3 southbound Ninth Avenue approach and westbound Mercer Street.

4 5.4 AM and PM Peak Hour Travel Times

5 Key Findings

- 6 • Travel times for the routes investigated generally are not projected to vary
7 much between the 2015 Baseline and Project scenarios, with the majority
8 of the times expected to be within 1 minute of each other.
- 9 • The largest travel time increases between 2015 Baseline and Project
10 conditions are expected to be on the Ballard-to-Duwamish (S. Spokane
11 Street) route. In the AM peak hour, this generally would be a 2 minute
12 increase, but could be up to an 8 minute increase in the PM in the
13 northbound direction for the Project using the Alaskan Way surface street.
14 However, in the Project scenario, using Mercer Street and the bored tunnel
15 to travel between these locations, the travel times are projected to be only
16 1 to 2 minutes slower in the AM peak hour, and are expected to be the
17 same or about 1 minute faster in the PM peak hour.
- 18 • Other routes show potential reductions in travel time as well. The greatest
19 reduction in travel time between 2015 Baseline and Project scenarios is
20 expected for the Woodland Park to S. Spokane Street route where up to a
21 1- to 4-minute decrease could be expected, depending on the direction and
22 time period considered.
- 23 • As expected, travel times would generally increase between 2015 and 2030
24 Project conditions due to background growth in traffic demand.
- 25 • The greatest increases in travel times between 2015 and 2030 noted in the
26 analysis results were for the Ballard to Duwamish and Northgate to
27 Boeing Access Road routes, with increases of up to 5 and 6 minutes
28 respectively.
- 29 • The Viaduct Closed (No Build Alternative) is expected to result in
30 substantially slower travel times in comparison to the other scenarios. As
31 an example, the Woodland Park to S. Spokane Street route is projected to
32 experience travel times three times longer than the other options.

33 AM and PM peak hour travel times for routes using the SR 99 corridor are
34 presented as a gauge for how efficient an alternative may be for providing
35 mobility during periods of high use. The travel time routes analyzed were shown
36 in Exhibit 2-8 in Chapter 2, Methodology. Travel times are described below for
37 the key regional routes that were deemed appropriate for representing the
38 primary travel patterns experienced on or adjacent to the corridor:

- 1 • South to/from downtown, represented by West Seattle to CBD via SR 99.
 - 2 • North to/from downtown via SR 99, represented by Woodland Park
 - 3 (SR 99 and N. 50th Street) to CBD.
 - 4 • Through trips on SR 99, represented by Woodland Park to S. Spokane
 - 5 Street.
 - 6 • Through trips on the Elliott/Western corridors, represented by Ballard
 - 7 Bridge to S. Spokane Street:
 - 8 a. via Alaskan Way (or AWWV if applicable).
 - 9 b. via Mercer Street, bored tunnel.
 - 10 • Northgate to Boeing Access Road via I-5.
 - 11 • Mercer Street: from I-5 to Elliott Avenue.
- 12 Exhibit 5-34 summarizes corridor travel times by route and direction. Exhibit 5-35
- 13 shows travel times for Option 2 for the two routes affected by the option: Ballard to
- 14 S. Spokane Street via Mercer Street and the bored tunnel, and Mercer Street from I-5 to
- 15 Elliott Avenue.

16 5.4.1 West Seattle to CBD

17 This route extends from the intersection of California Avenue and Alaska

18 Junction to the CBD (Fourth Avenue and Seneca Street) and is presented for the

19 peak direction trip only (i.e., inbound in the AM and outbound in the PM peak

20 period).

21 For this route, travel times would be very similar under the 2015 Baseline and

22 2015 Project scenarios. The travel time increase is largely because the selected

23 CBD destination is relatively close to the existing mid-town ramps. For travel

24 times to points in the south CBD and Pioneer Square area from West Seattle,

25 Project travel times would likely be faster.

26 Travel times between 2015 and 2030 Project scenarios generally would increase by

27 1 to 3 minutes.

28 5.4.2 Woodland Park to CBD

29 This route extends from N. 50th Street/SR 99 to downtown Seattle and is presented

30 for the peak direction movement only (i.e., southbound in the AM peak and

31 northbound in the PM peak).

32 As with the West Seattle to CBD route, similar travel times are expected for the

33 2015 Baseline and 2015 Project scenarios. For the 2030 Project scenario, travel

34 times would increase slightly compared to 2015 Project conditions.

1 Exhibit 5-34. Corridor Travel Times

Eastbound	6	n/a	8	8	11	n/a	10	14

2 Estimated travel times in minutes.

3 ¹ The Woodland Park to S. Spokane Street segment was also assessed for the Viaduct Closed (No Build
4 Alternative) scenario during the PM peak hour: 47 minutes southbound and 44 minutes northbound.
5

1 Exhibit 5-35. Corridor Travel Times for Routes Affected by Option 2

2 *(Table to be added when data are available)*

3

4

1 **5.4.3 Woodland Park to S. Spokane Street**

2 Travel times for this route are expected to decrease between 2015 Baseline and
3 2015 Project conditions. This is primarily due to improved traffic flow resulting
4 from consolidation and relocation of corridor ramps and improved roadway
5 geometry. In addition, the bored tunnel would be more direct (less distance) than
6 the existing viaduct. For this travel time route, a PM peak hour travel time was
7 also estimated for the Viaduct Closed (No Build Alternative), showing
8 dramatically higher (i.e., three times higher) travel times than for either the 2015
9 Baseline or Project. In the Viaduct Closed (No Build Alternative), the assumed
10 route through downtown was via Wall Street, Second Avenue, Madison Street,
11 and Alaskan Way.

12 From 2015 to 2030 (Project scenarios), travel times would generally increase based
13 on background growth in traffic demand.

14 **5.4.4 Ballard Bridge to S. Spokane Street (via AWV and/or Alaskan Way)**

15 This route reflects the travel times that trips to and from Ballard and Interbay
16 would experience.

17 With the removal of the Elliott Avenue and Western Avenue access ramps
18 to/from SR 99 under the 2015 Project scenario, travel times are expected to
19 increase over 2015 Baseline conditions. The use of the existing Alaskan Way
20 surface arterial for Project conditions is estimated to result in a 2 minute increase
21 in travel time for both directions in the AM peak hour. In the PM peak hour,
22 travel times are projected to be about 2 minutes longer in the southbound
23 direction and 8 minutes longer in the northbound direction. By the 2030 horizon,
24 travel times would remain similar to 2015 Project conditions or increase
25 marginally by up to 3 minutes. Note that a large share of the peak period delay
26 for general purpose traffic experienced along this route under both the Baseline
27 and Project scenarios occurs on Elliott Avenue north of Denny Way and is related
28 to the conversion of a general purpose lane to a transit lane during the peak
29 periods.

30 **5.4.5 Ballard Bridge to S. Spokane Street (via Mercer Street and Bored Tunnel)**

31 This route uses Elliott Avenue to W. Mercer Place, takes Mercer Street to access
32 the bored tunnel via either Sixth Avenue (to SR 99) or Dexter Avenue (from
33 SR 99) and the new ramps at Republican Street. Since this path would not exist
34 under 2015 Baseline conditions, only an estimation of 2015 and 2030 Project
35 conditions is provided. As shown in the exhibit above, travel times for this path
36 compare favorably for the 2015 Project when compared to the surface Alaskan
37 Way path, i.e., this path is up to 9 minutes faster than the surface Alaskan Way

1 path in the northbound direction in the PM peak hour. In the AM peak hour, this
2 path is still expected to be slightly slower than the 2015 Baseline path via
3 Elliott/Western Avenues and the viaduct; however, this path is estimated to be
4 slightly faster than the Baseline in the PM peak hour northbound direction.

5 Travel times on the Mercer Street/bored tunnel path would generally increase
6 between 2015 and 2030, based on higher traffic levels and associated mainline
7 friction. Travel time increases in the PM peak hour would be more pronounced
8 overall.

9 5.4.6 Northgate to Boeing Access Road (via I-5)

10 Travel times between Northgate and Boeing Access Road are generally the
11 highest of any route examined, primarily due to the distance covered along the
12 route. The results of the operational analysis show that implementation of the
13 project elements by the 2015 horizon would not affect travel times noticeably
14 compared to 2015 Baseline conditions. In fact, travel time differences between
15 2015 Baseline and Project conditions are expected to be less than 1 minute, on
16 average. However, by the 2030 horizon year travel times for Project conditions
17 would likely increase due to background traffic growth, with the most
18 pronounced increases occurring during the PM peak hour.

19 5.4.7 Mercer Street (I-5 to Elliott Avenue)

20 East-west travel times for the Mercer Street corridor are generally similar for both
21 2015 Baseline and 2015 Project conditions. As part of the initial changes for
22 Mercer Street under the 2015 Baseline scenario, the segment between Fairview
23 Avenue and Eighth Avenue is converted to two-way. With the additional
24 segment of Mercer Street converted to two-way operations between Eighth
25 Avenue and Fifth Avenue N. under the 2015 Project scenario, some changes in
26 travel times are expected as a result in changes in travel patterns and operational
27 changes along the corridor. For the AM peak hour, travel times are expected to
28 increase slightly from 2015 Baseline to 2015 Project conditions for both directions.
29 However, the reverse is expected for eastbound traffic during the PM peak hour,
30 when travel times may decrease slightly. For the 2030 Project conditions, travel
31 times would generally be higher than for the 2015 Project scenario.

32 5.5 Roadway Connectivity and Access

33 This section gauges the provision and quality of connections between the SR 99
34 corridor and other streets and highways in the study area.

1 Key Findings

- 2 • Connections to SR 519 and local streets in the stadium area are improved
3 under the Baseline and Project scenarios by providing new access to
4 southbound SR 99 and from northbound SR 99 through the S. Holgate
5 Street to S. King Street Viaduct Replacement Project, and further enhanced
6 by this project.
- 7 • The Project would relocate access to SR 99 south of downtown.
8 Connections would be provided from northbound SR 99 to Alaskan Way
9 (and other arterial streets) and from Alaskan Way to southbound SR 99
10 south of S. King Street near S. Plummer Street. These ramps would
11 provide improved access to the stadium area, central waterfront, Pioneer
12 Square and southern portions of downtown compared to existing
13 conditions, but mid-town locations would be accessed by surface streets
14 rather than direct ramps from the viaduct.
- 15 • The northbound off-ramp to Western Avenue and southbound on-ramp
16 from Elliott Avenue would be removed under the Bored Tunnel
17 Alternative. SR 99 trips to and from northwest Seattle communities
18 (Ballard, Magnolia, Belltown) would have several choices. One option
19 would be to exit/enter SR 99 on the Alaskan Way ramps (at Plummer
20 Street) and continue on Alaskan Way or other downtown arterials to reach
21 the Elliott/Western corridor in Belltown. Another option would be to
22 continue through the bored tunnel to the South Lake Union access point at
23 Republican Street and then use Mercer Street or Harrison Street, Broad
24 Street and Denny Way to reach the Elliott/Western corridor.
- 25 • The lightly used Battery Street ramps immediately adjacent to the Battery
26 Street Tunnel would be closed. New consolidated ramps at Aurora
27 Avenue/Denny Way would provide for this access under the Project.
- 28 • Connections in the South Lake Union and Queen Anne areas would be
29 improved for the Bored Tunnel Alternative, which includes reconnecting
30 several east-west arterial streets that are severed today. Connections to
31 SR 99 would be provided by new ramps at Republican Street or via
32 arterial connections north of Mercer Street (similar to existing conditions
33 in those locations).
- 34 • Exhibit 5-36 details the connections to and from SR 99 for the existing
35 facility, 2015 Baseline, and the 2015/2030 Project scenarios.

1 SB = southbound, NB = northbound, EB = eastbound, WB = westbound.
2

3 **5.5.1 2015 Baseline**

4 The S. Holgate Street to S. King Street Viaduct Replacement Project is being
5 completed prior to 2015 and is included in the 2015 Baseline conditions. The
6 primary access difference between the 2005 existing facility and the 2015 Baseline
7 facility is that new ramps to southbound SR 99 and from northbound SR 99
8 would be provided from Alaskan Way at S. King Street. In addition, by 2015, the
9 Mercer Street project would have converted Mercer Street to two-way traffic flow

1 between I-5 and Dexter Avenue N. and would have disconnected Broad Street
2 from Ninth Avenue N. and reconnected it to Mercer Street at Eighth Avenue N.,
3 which would improve access to the arterial connections to Aurora Avenue.

4 5.5.2 Viaduct Closed (No Build Alternative)

5 In Scenario 1 of the Viaduct Closed (No Build Alternative) with a sudden
6 unplanned closure, the viaduct and ramps at First Avenue S., Columbia Street,
7 Seneca Street, Elliott Avenue, and Western Avenue would be closed. In Scenario
8 2 with catastrophic failure and collapse of the viaduct, the same viaduct and ramp
9 structures would be closed, but in addition, the surface streets under the viaduct
10 would also be unusable. In addition to the roadway directly under the viaduct,
11 this would include the portions under the viaduct and ramps for the following
12 streets:

- 13 • Railroad Way S.
- 14 • S. King Street
- 15 • S. Jackson Street
- 16 • S. Main Street
- 17 • S. Washington Street
- 18 • Yesler Way
- 19 • Columbia Street
- 20 • Marion Street
- 21 • Madison Street
- 22 • Spring Street
- 23 • Seneca Street
- 24 • University Street
- 25 • Elliott Avenue
- 26 • Blanchard Street
- 27 • Bell Street
- 28 • Western Avenue

29 With the above roadways closed, traffic backups would likely hinder adjacent
30 roadways within the Center City area. The overall effect is that the Viaduct
31 Closed (No Build Alternative) would severely inhibit roadway connectivity and
32 access in the Center City area; Scenario 2 would have a more dramatic impact
33 than Scenario 1.

1 **5.5.3 To and From Stadium Area/SR 519**

2 With the Project, access to the stadium area would be provided by a new
3 interchange connecting to Alaskan Way, S. Royal Brougham Way and the East
4 Frontage Road. Access from southbound SR 99 and to northbound SR 99 would
5 be maintained under the alternative, though relocated from First Avenue S. to
6 ramps that connect to the East Frontage Road in the vicinity of S. Royal Brougham
7 Way. Access to and from the south would be via new ramps connecting to
8 Alaskan Way at S. Plummer Street. S. Royal Brougham Way would end east of
9 SR 99 at its intersection with the SR 99 southbound off-ramp and SR 99
10 northbound on-ramp.

11 **5.5.4 To and From Downtown Seattle**

12 With the Bored Tunnel Alternative, the ramps to downtown would not be
13 provided at their current locations. Instead, access would be provided from
14 northbound SR 99 to Alaskan Way, and from Alaskan Way to southbound SR 99
15 south of S. King Street near S. Plummer Street. The removal of the downtown
16 ramps would alter traffic patterns, and the Alaskan Way surface street would be
17 expected to carry additional traffic to and from the CBD and the stadium area.

18 An advantage of this configuration is that the interchange location is better able to
19 accommodate traffic flows than the current Columbia and Seneca Street ramp
20 locations. Additionally, traffic would be able to distribute from Alaskan Way to
21 the downtown street grid using any of several cross streets, including S. Jackson
22 Street, S. Main Street, Yesler Way, and Columbia, Marion, Madison, and Spring
23 Streets, rather than being concentrated in single locations.

24 Because the stadium area ramps would be less centrally located to downtown
25 than the existing ramps, trips destined for the central and northern portions of
26 downtown would have to travel a few additional blocks on arterial streets rather
27 than on SR 99. Trips to and from the southern areas of downtown would find
28 that the stadium area ramps provides more direct access, however. In addition,
29 access to SR 99 for trips to and from ferry service at Colman Dock would be more
30 direct with the stadium area ramps under the Bored Tunnel Alternative than it is
31 with the Seneca and Columbia Street ramps today.

32 **5.5.5 To and From Belltown/Interbay**

33 The northbound off-ramp to Western Avenue and southbound on-ramp from
34 Elliott Avenue would both be removed under the Bored Tunnel Alternative.
35 Trips that currently use these ramps may instead exit/enter SR 99 on the Alaskan
36 Way ramps (at S. Plummer Street) and continue on Alaskan Way or other
37 downtown arterials to reach the Elliott/Western corridor in Belltown. Another

1 option is to use Mercer Street or Denny Way and Broad Street to access SR 99 at
2 Republican Street and continue through the bored tunnel.

3 In addition, the lightly used and geometrically substandard Battery Street ramps
4 immediately adjacent to the Battery Street Tunnel would be closed with the
5 decommissioning of the Battery Street Tunnel. The Harrison Street ramps from
6 Aurora Avenue provide good access for these trips.

7 5.5.6 To and From Mercer (South Lake Union Area)

8 For the Bored Tunnel Alternative, access in the South Lake Union and Uptown
9 areas would be maintained, with enhanced levels of safety compared to the
10 existing configuration. SR 99 would be lowered from the Battery Street Tunnel to
11 approximately Mercer Street. Arterial connections directly to SR 99 in this
12 segment would no longer be provided; instead, access would be consolidated to
13 ramps at Harrison Street and Republican Street. A deceleration lane would be
14 provided for the northbound off-ramp, and an acceleration lane for the
15 southbound on-ramp, which represents a considerable operational improvement
16 over the right angle turns on and off the facility serving these movements today.

17 South of Mercer Street, access on and off SR 99 would be provided at Harrison
18 Street and Republican Street. The street grid would be connected over the top of
19 SR 99 at John, Thomas, and Harrison Streets. Broad Street would be closed
20 between Taylor Avenue N. and Ninth Avenue N. so that the street grid could be
21 reconnected. Mercer Street would continue to cross under SR 99 as it does today,
22 but it would be widened and converted to a two-way street with three lanes in
23 each direction and a center turn lane.

24 North of Mercer Street, arterial connections to SR 99 would not change from the
25 existing facility.

26 5.6 Transit Services

27 This section identifies the expected effects on transit services using both
28 qualitative and quantitative information. These effects include expected changes
29 in ridership, transit routing, coverage area, and potential effects on travel time
30 along major transit corridors that could be affected by the project.

31 Travel model results were used to determine potential travel time effects on bus
32 routes operating along SR 99 to downtown Seattle. The transit corridors include
33 the Aurora Avenue corridor between Woodland Park and downtown Seattle,
34 Ballard and downtown Seattle, West Seattle and downtown Seattle, and Burien
35 and downtown Seattle. Three of the transit corridors have been identified for
36 enhanced RapidRide service: Ballard, Aurora Avenue, and West Seattle.

1 Key Findings

- 2 • Under the Bored Tunnel Alternative, transit access for bus routes
3 operating between South King County/West Seattle and downtown Seattle
4 would no longer be available at the Columbia and Seneca Street ramps.
5 Transit routes would likely access downtown to and from the stadium
6 area ramps at the north end of the new S. Holgate Street to S. King Street
7 Viaduct Replacement Project elevated facility. A shoulder transit lane
8 would be provided on northbound SR 99 from approximately S. Holgate
9 Street to the end of the stadium area off-ramp to allow transit vehicles to
10 bypass potential queues emanating from the ramp terminus intersection.
11 Routes would then continue north on Alaskan Way to connect to the
12 downtown street grid.
- 13 • In the north end, under the Bored Tunnel Alternative, the SR 99 right side
14 on- and off-ramps to/from Denny Way would be relocated to left-side
15 ramps to Harrison Street and Aurora Avenue, ultimately connecting to
16 Denny Way. Buses operating along Aurora Avenue would likely use this
17 left-side exit to access downtown Seattle. On Aurora Avenue, right-side
18 transit lanes would be provided between Harrison Street and Wall Street
19 to facilitate transit flow through this area.
- 20 • Additional locations in the South Lake Union area could be served by
21 transit using new access opportunities, and the Bored Tunnel Alternative
22 would also improve pedestrian access to transit since it provides for
23 pedestrian crossings of Aurora Avenue.
- 24 • General purpose traffic travel times were assessed to provide an
25 indication of possible transit travel times. With the Bored Tunnel
26 Alternative, peak hour travel times for inbound trips along selected transit
27 corridors would be generally comparable to Baseline conditions for
28 inbound trips. For those trips involving higher travel times with the
29 Bored Tunnel Alternative versus Baseline, the greatest variations are
30 generally between 5 and 6 minutes.
- 31 • The relatively higher travel time differences between the Baseline and the
32 Bored Tunnel Alternative involve outbound trips. For outbound trips
33 between downtown Seattle and West Seattle or Burien, this additional
34 travel time would likely be attributable to vehicles having to pass through
35 more signalized intersections under the Bored Tunnel Alternative as
36 compared to Baseline conditions, which provides access to SR 99 within
37 downtown.
- 38 • The highest time differential for the West Seattle and Burien corridors was
39 for outbound trips in the AM peak hour. This is the off-peak direction and
40 would carry significantly fewer riders.

- 1 • Outbound PM peak hour trips between downtown Seattle and Ballard for
2 general purpose trips may increase somewhat under the Bored Tunnel
3 Alternative due to added congestion at the Mercer Place intersection with
4 Elliott Avenue; this would be caused by an expected increase in southbound
5 left turns. However, these times apply to general traffic; transit vehicles
6 would benefit from the peak period transit lane on Elliott Avenue, which
7 would likely minimize any travel time differences between the scenarios.
- 8 • Peak hour travel times for inbound bus trips accessing downtown Seattle
9 from Ballard are expected to be generally similar between the Bored
10 Tunnel Alternative and Baseline scenarios.
- 11 • Peak hour travel times for inbound bus routes accessing downtown Seattle
12 from West Seattle are expected to be generally similar for the 2015 Baseline
13 and the Bored Tunnel Alternative. For outbound buses there would be
14 additional travel time of between 1 and 4 minutes for the Bored Tunnel
15 Alternative versus Baseline.
- 16 • In the Aurora Avenue corridor (Woodland Park/downtown Seattle), peak
17 hour travel times for Baseline and the Bored Tunnel Alternative would be
18 somewhat similar, with the Bored Tunnel Alternative trips averaging
19 slightly faster.
- 20 • Peak hour travel times for inbound bus trips accessing downtown Seattle
21 from Burien are expected to be generally similar for the 2015 Baseline and
22 the Bored Tunnel Alternative.
- 23 • For some trips in the peak hour, transit vehicles would experience a relatively
24 small amount of added travel time under the Bored Tunnel Alternative as
25 compared to the Baseline. However, the extent of added travel time would
26 not likely require added resources in terms of more buses on the affected bus
27 routes.

28 5.6.1 Modeled Transit Ridership

29 Exhibit 5-37 summarizes projected daily transit ridership at three screenlines.
30 AM peak period transit ridership is summarized in Exhibit 5-38.

31 Exhibit 5-37. Model-Estimated Daily Transit Ridership (person-trips) at Selected Screenlines

	Existing (2005)	2015 Baseline	2015 Viaduct Closed (No Build Alternative)	2015 Project	2030 Project
South (South of S. King Street)	56,480	98,900	95,600	95,840	165,320
Central (North of Seneca Street)	90,220	126,270	120,500	124,170	180,280
North (North of Thomas Street)	90,020	118,750	119,120	118,640	172,550

1 Exhibit 5-38. Model-Estimated AM Peak Period Transit Ridership (person-trips) at
 2 Selected Screenlines

	Existing (2005)	2015 Baseline	2015 Viaduct Closed (No Build Alternative)	2015 Project	2030 Project
South (South of S. King Street)	18,210	31,250	30,650	30,330	54,990
Central (North of Seneca Street)	26,940	36,320	35,450	36,050	53,670
North (North of Thomas Street)	29,310	36,330	36,570	36,340	53,750

3

4 Transit Ridership Growth between 2005 and 2015 - Baseline and Project Conditions

5 Between 2005 and 2015, projected daily transit demand in the Baseline scenario
 6 represents increases ranging from 32 percent at the north screenline to 75 percent
 7 in the south. The increases for the AM peak period are slightly higher, ranging
 8 from 24 percent at the north screenline to 68 percent at the south screenline.

9 These increases reflect a variety of transit improvements expected to be
 10 implemented between the 2005 existing condition and 2015, including Link light
 11 rail to the south to Sea-Tac Airport and north to the University of Washington,
 12 and King County Metro’s RapidRide BRT service from West Seattle, Ballard, and
 13 North Seattle.

14 Ridership growth between 2005 and 2015 with the project would generally be
 15 similar or slightly lower than Baseline depending on the screenline. For the north
 16 screenline, daily transit ridership with the project would be similar to Baseline
 17 ridership. For the central and south screenlines, daily transit ridership in 2015
 18 with the Project would be slightly less (between 2 and 3 percent) than with the
 19 Baseline. AM peak period transit ridership in 2015 for Baseline and Project would
 20 have generally similar patterns as total daily demand.

21 The slight decrease in transit demand between Baseline and 2015 Project at the
 22 central and south screenlines would be likely due to anticipated changes in transit
 23 access in south downtown. With the project, bus routes from West Seattle and
 24 South King County would exit to downtown farther south than the current access
 25 locations at Columbia and Seneca Streets. While this routing change would
 26 expand the bus service coverage, it would also increase travel times for some
 27 riders. Different bus routing assumptions or arterial transit priority
 28 enhancements to improve bus travel times could potentially provide sufficient
 29 benefit to offset the relatively small projected decrease in transit ridership relative
 30 to Baseline conditions.

31 The relatively small variations in 2015 transit ridership at screenlines for the
 32 Baseline, Project, and Viaduct Closed (No Build Alternative) scenarios would also
 33 be reflected in mode shares for Seattle Center City. These shares, further

1 discussed below under Transit Mode Share, would be about 36.0 percent for
2 home-based work trips and about 9.5 percent for non-work trips.

3 **2015 Viaduct Closed (No Build Alternative) Conditions**

4 For the north screenline, 2015 transit ridership under Viaduct Closed (No Build
5 Alternative) conditions would approximate the volumes under 2015 Baseline and
6 2015 Project conditions. The 2015 Viaduct Closed (No Build Alternative) transit
7 ridership at the central screenline would be approximately 5 percent lower than
8 Baseline and 3 percent lower than the Project. Without the viaduct, the congested
9 conditions of surface streets would affect the ability of bus routes to meet
10 demand. At the south screenline, the volumes for 2015 Viaduct Closed (No Build
11 Alternative) conditions would be approximately 3 percent lower than Baseline
12 but would approximate levels under the Project.

13 **2030 Project Conditions**

14 By 2030, total daily transit ridership in the study area is forecasted to increase
15 substantially—about an additional 45 percent over 2015 Baseline and Project
16 levels for the north and central screenlines, and roughly 70 percent for the south
17 screenline. By 2030, transit riders would be able to use existing and new bus
18 routes as well as new rail services (Link light rail and Sounder commuter rail,
19 with each expanded according to the ST2 Plan) provided by Sound Transit.
20 Expanded transit services would affect transit demand at each screenline.

21 By 2030, AM peak period transit ridership in the study area is also forecasted to
22 increase over 2015 levels—by nearly 50 percent for the north and central
23 screenlines. For the south screenline, the AM increase in peak period transit
24 ridership between 2015 and 2030 would be from 75 to 80 percent, or from about
25 31,000 to almost 55,000.

26 **Transit Mode Share**

27 The projected transit ridership for 2015 and 2030 indicates gradually increasing
28 shares of transit ridership under the Baseline and the Bored Tunnel Alternative.
29 The transit shares for 2005, 2015, and 2030 are identified in Exhibit 5-39. The
30 extent of ridership growth by 2015 and 2030 would be such that transit shares of
31 total travel are expected to increase substantially. Expanded bus and rail service,
32 particularly Link light rail service in place by 2030, would contribute to this
33 growth in transit mode shares.

34 The transit share of home-base work trips (i.e., commuting to work) is estimated
35 to grow between 2005 and 2030 from 33 percent of total trips to almost 47 percent.
36 Under potential 2015 scenarios, the transit share would grow to about 36 percent
37 for Baseline, Viaduct Closed (No Build Alternative), and Project scenarios.

1 Between 2005 and 2030, the transit share of non-work trips is estimated to grow
 2 from 8.8 to 11.1 percent of total travel. Under potential 2015 scenarios, the transit
 3 share for non-work trips would grow to about 9.5 percent for Baseline, Viaduct
 4 Closed (No Build Alternative), and Project scenarios.

5 **Exhibit 5-39. Model-Estimated Daily Transit Mode Shares (person-trips) – To/From**
 6 **Seattle Center City**

	Existing (2005)	2015 Baseline	2015 Viaduct Closed (No Build Alternative)	2015 Project	2030 Project
Home-Based Work	33.3	36.3	36.4	36.1	46.9
Non-Work	8.8	9.5	9.4	9.4	11.1

7

8 **5.6.2 Transit Vehicle Connections**

9 **2015 Baseline**

10 Access from SR 99 to the central part of downtown Seattle would continue to be
 11 provided at the Columbia Street on-ramp and Seneca Street off-ramp, in addition
 12 to access provided at the stadium area ramps.

13 For buses accessing downtown Seattle from the north end, existing access
 14 locations would be maintained. No additional access locations would be
 15 provided for buses.

16 **2015 Bored Tunnel Alternative**

17 Under the Bored Tunnel Alternative, existing access ramps at Seneca and
 18 Colombia Streets would no longer be available. Transit vehicles traveling on
 19 SR 99 from West Seattle and South King County would use the new ramps
 20 located at the stadium area, and then travel north on Alaskan Way. A shoulder
 21 transit lane on northbound SR 99 from approximately S. Holgate Street to the end
 22 of the stadium area off-ramp would allow transit vehicles to bypass potential
 23 queues emanating from the ramp terminus intersection. With the new stadium
 24 area ramps, transit vehicles traveling on SR 99 to the south end of downtown
 25 Seattle would have improved access to locations in the SODO area as well as in
 26 Pioneer Square and south downtown. Buses would turn on S. Main Street or
 27 other east-west streets, and then on one of the primary north-south corridors to
 28 access the downtown street grid.

29 The access from the stadium area ramps would extend transit service coverage to
 30 a greater portion of the area south of the downtown Seattle core in comparison to
 31 existing conditions. This access would be complemented by improved street
 32 facilities in the south end, including three new east-west streets between S. Royal

1 Brougham Way and S. King Street: S. Plummer Street, S. Charles Street, and
2 S. Dearborn Street.

3 For transit vehicles serving downtown Seattle from the north, the Denny Way
4 ramps would be replaced with ramps to Harrison Street and Aurora Avenue,
5 providing a similar connection to Denny Way. Buses operating along Aurora
6 Avenue would likely use this left-side exit to access downtown Seattle. On
7 Aurora Avenue, right-side transit lanes would be provided between Harrison
8 Street and Wall Street to facilitate transit flow through this area. The Bored
9 Tunnel Alternative would also provide added traffic and pedestrian access across
10 Aurora Avenue in the South Lake Union area. New east-west streets would
11 connect Thomas, John, and Harrison Streets. The extension of Sixth Avenue N. to
12 Mercer Street would improve access to southbound SR 99 from Mercer Street.
13 These access improvements provide opportunities for potential new transit
14 connections in South Lake Union as well as improved pedestrian access to transit.

15 5.6.3 Peak Hour Travel Times for Transit Corridors

16 The following sections identify estimated travel times for several transit corridors
17 serving downtown Seattle. The travel demand information for 2015 does not
18 identify transit-specific travel times. However, the information for general traffic
19 does allow comparisons between scenarios for major transit corridors. Also, for
20 segments of roadways that would have transit lanes, information is available on
21 speeds and travel times for buses along with those for general purpose traffic in
22 the same segments.

23 Travel time variations between the Baseline and the Bored Tunnel Alternative are
24 summarized in Exhibit 5-40. The variations are presented for the four major
25 transit corridors that could be affected by changes under the Bored Tunnel
26 Alternative.

27 Peak Hour Travel Times – Ballard/Downtown Seattle

28 The estimated travel times in 2015 for general traffic along Elliott Avenue
29 between the Ballard Bridge and Denny Way for the Baseline and Bored Tunnel
30 Alternative are shown in Exhibit 5-40. For most trips, travel time with the Bored
31 Tunnel Alternative would be generally the same as for the Baseline. At 2 minutes,
32 the time difference for PM outbound trips reflects a slight travel time increase.
33 This increase is primarily due to the added time it is expected to take for
34 northbound traffic to travel through the Elliott Avenue/Mercer Place intersection
35 due to the projected increase in southbound left turns. Note that the existing BAT
36 lanes on Elliott Avenue would provide travel time advantages for transit through
37 this corridor. Hence, most of the differences in travel time expected between the

1 Baseline and the project for general purpose traffic along this route would not
 2 apply to transit travel times.

3 **Exhibit 5-40. 2015 Travel Times¹ Along Major Transit Travel Corridors**

	Baseline	Project	Change	Baseline	Project	Change
	AM Peak Hour			PM Peak Hour		
Ballard to CBD²						
Inbound	8	8	0	8	7	-1
Outbound	7	7	0	12	14	+2
Aurora Avenue (Woodland Park to CBD)						
Inbound	19	18	-1	19	19	0
Outbound	11	12	+1	17	17	0
West Seattle to CBD						
Inbound	21	22	+1	20	17	-3
Outbound	12	17	+5	24	25	+1
Burien to CBD						
Inbound	24	25	+1	16	19	+3
Outbound	14	20	+6	22	27	+5

4 ¹ Travel times are in minutes for general purpose traffic.

5 ² Represented by travel on Elliott Avenue between the Ballard Bridge and Denny Way.

6 **Peak Hour Travel Times – Aurora Avenue Corridor (Woodland Park/Downtown Seattle)**

7 The estimated general purpose travel times in 2015 along the Aurora Avenue
 8 corridor for the Baseline and Bored Tunnel Alternative are shown in Exhibit 5-40.
 9 With the Bored Tunnel Alternative, the right-side Denny Way ramps on Aurora
 10 Avenue would be replaced with left-side ramps to and from Harrison Street.
 11 Additionally, right-side transit lanes would be provided along Aurora Avenue in
 12 both directions between Harrison and Wall Streets, providing transit priority
 13 through the critical Denny Way intersection. With peak hour travel time
 14 differences of approximately 1 minute or less, conditions along the Aurora
 15 Avenue corridor with the project would be generally comparable to the Baseline.

16 **Peak Hour Travel Times – West Seattle/Downtown Seattle Corridor**

17 The estimated travel times in 2015 along the West Seattle/downtown Seattle
 18 corridor for the Baseline and Project are shown in Exhibit 5-40. With the Bored
 19 Tunnel Alternative, direct access to downtown Seattle via Columbia and Seneca
 20 Streets would no longer be available. Some additional travel time for bus routes
 21 operating between West Seattle and downtown Seattle would be anticipated. The
 22 most variation in travel times between 2015 Baseline and 2015 Project involves
 23 outbound trips in the AM peak. For outbound trips in the AM peak, travel time
 24 under the Bored Tunnel Alternative is expected to be 5 minutes longer as
 25 compared to the Baseline. For the Bored Tunnel Alternative, traffic has to pass

1 through more signalized intersections to reach the southbound on-ramp in the
2 stadium area. However, this highest time differential occurs in the off-peak
3 direction, which involves substantially fewer riders than AM inbound travel.

4 Travel time benefits are also expected for transit vehicles due to the provision of
5 the shoulder transit lane for northbound SR 99 between approximately S. Holgate
6 Street and the off-ramp terminus. In the AM peak hour, travel speeds in the
7 shoulder transit lane are estimated at 36 mph as compared to 34 mph for travel in
8 the general purpose lane. In the PM peak hour travel speeds in the shoulder
9 transit lane are estimated at 41 mph as compared to 39 mph for travel in the
10 general purpose lane.

11 For the PM peak, travel time differences between Baseline and the project are
12 generally estimated to be 3 minutes or less. For inbound trips, travel time under
13 the project would be about 3 minutes shorter than Baseline, while for the more
14 heavily traveled outbound trips, travel time under the project would be roughly
15 1 minute longer than the Baseline. The longer travel time in the Baseline is likely
16 due to the impacts of the queues from the northbound Western Avenue off-ramp,
17 which spill back onto the SR 99 mainline and impede the traffic exiting at Seneca
18 Street.

19 Peak Hour Travel Times – South King County (Burien)/Downtown Seattle Corridor

20 With the Bored Tunnel Alternative, direct access to downtown Seattle via
21 Columbia Street and Seneca Street would no longer be available. For inbound
22 trips, the travel times under the Bored Tunnel Alternative and Baseline would be
23 generally similar. Greater variations in travel times between the Bored Tunnel
24 Alternative and Baseline would occur for outbound trips. The greatest variation
25 involves AM outbound trips, with travel time under the Bored Tunnel Alternative
26 estimated at approximately 6 minutes longer than under Baseline conditions. The
27 faster time for Baseline is likely because this is the off-peak direction for the AM
28 period and SR 99 southbound is expected to flow at relatively high speeds. For
29 the Bored Tunnel Alternative traffic has to pass through more signalized
30 intersections to reach the southbound on-ramp in the stadium area. Even though
31 this is the off-peak direction, the additional signalized intersections result in
32 additional delay for the Bored Tunnel Alternative. However, because this is the
33 off-peak direction it affects relatively fewer riders than the AM inbound direction
34 trips. Also, buses operating between Burien and downtown Seattle would benefit
35 from the shoulder transit lane on SR 99 between S. Holgate and S. King Streets in
36 terms of lower travel time. In the AM peak hour, travel speeds in the shoulder
37 transit lane are estimated at 36 mph as compared to 34 mph for travel in the
38 general purpose lane. In the PM peak hour, travel speeds in the shoulder transit

1 lane are estimated at 41 mph as compared to 39 mph for travel in the general
2 purpose lane.

3 5.6.4 Level of Service Changes Affecting Transit

4 In addition to travel time changes along key corridors, transit service could also
5 be affected by LOS changes at intersections with bus operations. At several
6 locations the LOS would be generally the same in 2015 with the Project as
7 compared to the Baseline, and in some cases, conditions would be improved. In a
8 few cases, conditions would be at LOS F or fall below LOS D with the project.
9 The following sections summarize results for selected locations.

10 At the south end of downtown Seattle, reduced LOS is projected for AM peak
11 hour trips at First Avenue S. and Yesler Way with the Project (LOS D) compared
12 to 2015 Baseline (LOS B). In the PM peak hour, the intersection would be LOS F
13 with the Project as compared to LOS E under the Baseline. The intersection of
14 Fourth Avenue S. and S. Royal Brougham Way would be LOS C in the AM peak
15 hour for both the Project and 2015 Baseline. For PM peak hour trips, the 2015 LOS
16 would be E for both the Project and Baseline.

17 At the north end of downtown Seattle, the intersection of Fifth Avenue N. and
18 Mercer Street in the AM peak hour would be at LOS A in 2015 Baseline but LOS D
19 with the Project. In the PM peak hour, this intersection would be at LOS C in the
20 Baseline and LOS E with the Project. The intersection of Dexter Avenue N. and
21 Mercer Street in the AM peak hour would be LOS C in the Baseline as compared
22 to LOS D with the Project. In the PM peak hour, this intersection would be LOS D
23 in the Baseline and LOS E with the Project.

24 5.6.5 High-Capacity Transit, HOV, and Enhanced Bus Service

25 Under the 2015 Bored Tunnel Alternative, a shoulder transit lane would be
26 provided on northbound SR 99 from approximately S. Holgate Street to the end of
27 the stadium area off-ramp to allow transit vehicles to bypass potential queues
28 emanating from the ramp terminus intersection. Additionally, in the north end
29 right-side arterial, transit lanes would be provided on Aurora Avenue between
30 Harrison and Wall Streets to facilitate transit flow through this area. The primary
31 benefit of this transit lane is anticipated to be providing priority for transit
32 through the Denny Way intersection. Under both the Baseline and Project, BAT
33 curb lanes are provided in both directions between W. Harrison and Wall Streets.

1 5.7 Truck Traffic and Freight

2 Key Findings

- 3 • Freight connections between SR 99 and streets in the SODO area,
4 including the stadium area ramps and E. Marginal Way, would be
5 improved under the Bored Tunnel Alternative.
- 6 • In the strictest sense, freight connections to the Interbay and BINMIC
7 areas are no longer provided on SR 99 at the north end of the central
8 waterfront (Elliott/Western ramps area). Freight traffic from Elliott/
9 Western would connect to Alaskan Way via Broad Street. Reconnection to
10 SR 99 in the south end of the central waterfront would occur roughly at
11 S. King Street. Alternatively, this freight traffic could also use Mercer
12 Street to access the bored tunnel via the Republican Street ramps.
- 13 • Ramp connections in the South Lake Union area would be revised
14 compared to today. Direct connections to Mercer Street (northbound) and
15 Broad Street (southbound) would be eliminated but would be replaced by
16 new connections to Republican Street and Harrison Street. These new
17 ramps would involve right turns onto the cross streets and would be
18 designed to accommodate truck movements.
- 19 • Option 2 would be less advantageous to freight mobility because trucks
20 would have to traverse longer grades on Mercer Street and on Sixth
21 Avenue N. than with Option 1.
- 22 • Hazardous and flammable cargo would be restricted from the bored
23 tunnel and would have to use either Alaskan Way or I-5 to move through
24 downtown.

25 5.7.1 Freight Connections

26 2015 Baseline

27 Freight traffic traveling on SR 99 to the south end of downtown Seattle would
28 have improved access to locations in the stadium/SODO area. These
29 improvements would be made possible by the reconfiguration of the interchange
30 under the S. Holgate Street to S. King Street Viaduct Replacement Project. A key
31 feature of this project would be the construction of an underpass for freight
32 coming to and from the Port of Seattle facilities along E. Marginal Way and
33 Alaskan Way.

34 In the central waterfront area, access restrictions on the Alaskan Way Viaduct
35 would remain in effect. Access from SR 99 to the central part of downtown
36 Seattle would continue to be provided at the Columbia Street on-ramp and
37 Seneca Street off-ramp.

1 For freight vehicles accessing downtown Seattle from the north end, existing
2 access locations would be maintained. No additional access locations would be
3 provided for freight vehicles.

4 2015 Bored Tunnel Alternative

5 In the south section, full connections for freight are provided between SR 99 and
6 the local arterial system around the stadium area. Northbound off-ramps and
7 southbound on-ramps are provided for freight trips that wish to access
8 downtown streets (or are excluded from using the bored tunnel) at S. Royal
9 Brougham Way.

10 Along the central waterfront, the Bored Tunnel Alternative would maintain
11 access to Alaskan Way from SR 99 for those freight trips serving the Interbay,
12 Magnolia, Ballard, and Fremont areas. While the existing connections on SR 99 at
13 Elliott Avenue/Western Avenue would no longer exist for the Bored Tunnel
14 Alternative, freight could still connect to areas in northwest Seattle through
15 connections from Alaskan Way to Broad Street and then to Elliott and Western
16 Avenues. Travel times for freight would be slightly higher, as vehicles would
17 encounter signalized intersections along Alaskan Way. Alternatively, this
18 connection could also be made via the bored tunnel and Mercer Street.

19 In the north section, full connections would be provided between SR 99 and the
20 local arterial system. The northbound off-ramp to Mercer Street would be
21 replaced by a northbound off-ramp at Republican Street. Trucks would use this
22 ramp to access Mercer Street (via Dexter Avenue N.). Prior to the ramp, a
23 deceleration lane would be provided to slow traffic to safely navigate the ramp's
24 expected tight turning radius. Two options for accessing southbound SR 99 from
25 Mercer Street have been proposed, and each would have impacts on freight
26 operations. For both options, entering connections would be improved compared
27 to the side-street connections provided today.

28 Under Option 1, eastbound or westbound freight traffic would gain access to
29 southbound SR 99 via Sixth Avenue. After turning onto Sixth Avenue, freight
30 traffic would then turn left at the T-intersection at Republican Street. Traffic
31 would then proceed to the southbound on-ramp and then to SR 99, accessing the
32 tunnel at Republican Street. A signalized intersection at Mercer Street and
33 southbound Sixth Avenue would help facilitate access to the on-ramp for
34 westbound freight traffic.

35 Under Option 2, both eastbound and westbound freight traffic from Mercer Street
36 would be able to access southbound SR 99, although both directions present their
37 own sets of challenges. Eastbound traffic (west of Mercer Street) would turn right
38 onto Sixth Avenue, then left at the T-intersection at Republican Street. This is a

1 similar route as under Option 1, except that trucks would be required to travel
2 farther on the downgrade on Mercer Street, and subsequently farther on an
3 upgrade on Sixth Avenue, to reach the Republican Street on-ramp to southbound
4 SR 99. No left turns to Sixth Avenue from Mercer Street for westbound traffic
5 would be allowed. Westbound traffic would require a very circuitous path to
6 reach the southbound on-ramp. Westbound freight trips on Mercer Street would
7 instead need to turn left on Dexter Avenue N., turn right on Harrison Street, cross
8 SR 99 and turn right on Sixth Avenue to reach the Republican Street on-ramp.
9 Due to the number of turns and tight radii at the on-ramp, some trucks may
10 choose to bypass this maneuver and opt for another route through the corridor.

11 Overall, freight vehicles using the Mercer Street Underpass would encounter
12 grades on either side of SR 99, which may slow down these vehicles for a short
13 distance. Trucks may or may not choose to take alternate paths in this area due to
14 this condition.

15 5.7.2 Ability of Design to Facilitate Freight Operations

16 New connections in the South Lake Union area would be designed to adequately
17 accommodate turning trucks. In addition, with the closure of Broad Street east of
18 Taylor Avenue N., Mercer Street and Fifth Avenue N. would likely be designated
19 the major truck route through the area. The likely truck route connecting I-5 to
20 the waterfront would include Mercer Street (at I-5) to Fifth Avenue N., Fifth
21 Avenue N. to Broad Street, and Broad Street to Alaskan Way.

22 For the Bored Tunnel Alternative, restrictions on the transport of hazardous and
23 flammable materials, including heating oil, are anticipated. Trucks hauling
24 hazardous materials would likely be prohibited in the new tunnel at all times and
25 would be rerouted to either I-5 or Alaskan Way.

26 5.7.3 Freight Train Operations

27 Minimal impacts to rail operations are foreseen. Improvements to provide
28 separation between street and train traffic are provided by the S. Holgate Street to
29 S. King Street Viaduct Replacement Project. A primary objective of this project is
30 to minimize impacts to freight and passenger rail operations. If there were to be
31 closures of the rail line, they would be temporary.

32 5.8 Parking

33 Key Findings

- 34 • The Project would eliminate approximately 80 on-street parking spaces in
35 the south portal area. The majority of these spaces are along Railroad
36 Way S. between Alaskan Way and Occidental Avenue S.

- 1 • The Project would remove approximately 220 on-street spaces in the north
- 2 portal area. The affected spaces are predominately along John, Thomas,
- 3 and Harrison Streets, where the existing parallel parking would be
- 4 converted to travel lanes.
- 5 • The Project would remove about 250 off-street parking spaces in the south
- 6 portal area. Approximately 40 off-street spaces would be removed in the
- 7 north portal area.
- 8 • Existing parking under the viaduct would not be affected.
- 9 • There is no difference in parking effects between the two north portal area
- 10 options.

11 Exhibit 5-41 summarizes the potential parking effects for the proposed action.
 12 The proposed action would reduce the number of parking spaces as compared to
 13 existing conditions. The Bored Tunnel Alternative would not affect any parking
 14 spaces under the viaduct because the parking spaces would remain before and
 15 after viaduct removal. Effects to parking spaces under the viaduct during
 16 construction are covered in Chapter 6, Construction. Potential future removal of
 17 spaces related to the surface street reconfiguration component of the Program is
 18 discussed in Chapter 7, Cumulative Effects.

19 **Exhibit 5-41. Parking Effects of the Bored Tunnel Alternative**

	South Portal	North Portal	Total Spaces
Existing Conditions¹			
On-Street Spaces	210	300	510
Off-Street Spaces	250	40	290
Total Spaces Existing	460	340	800
Number of Spaces Removed			
On-Street Spaces	-80	-220	300
Off-Street Spaces	-250	-40	-290
Under the viaduct	0	0	0
Net Change	-330	-260	-590

20 ¹ Spaces within the project boundaries.

21 **5.8.1 South Portal**

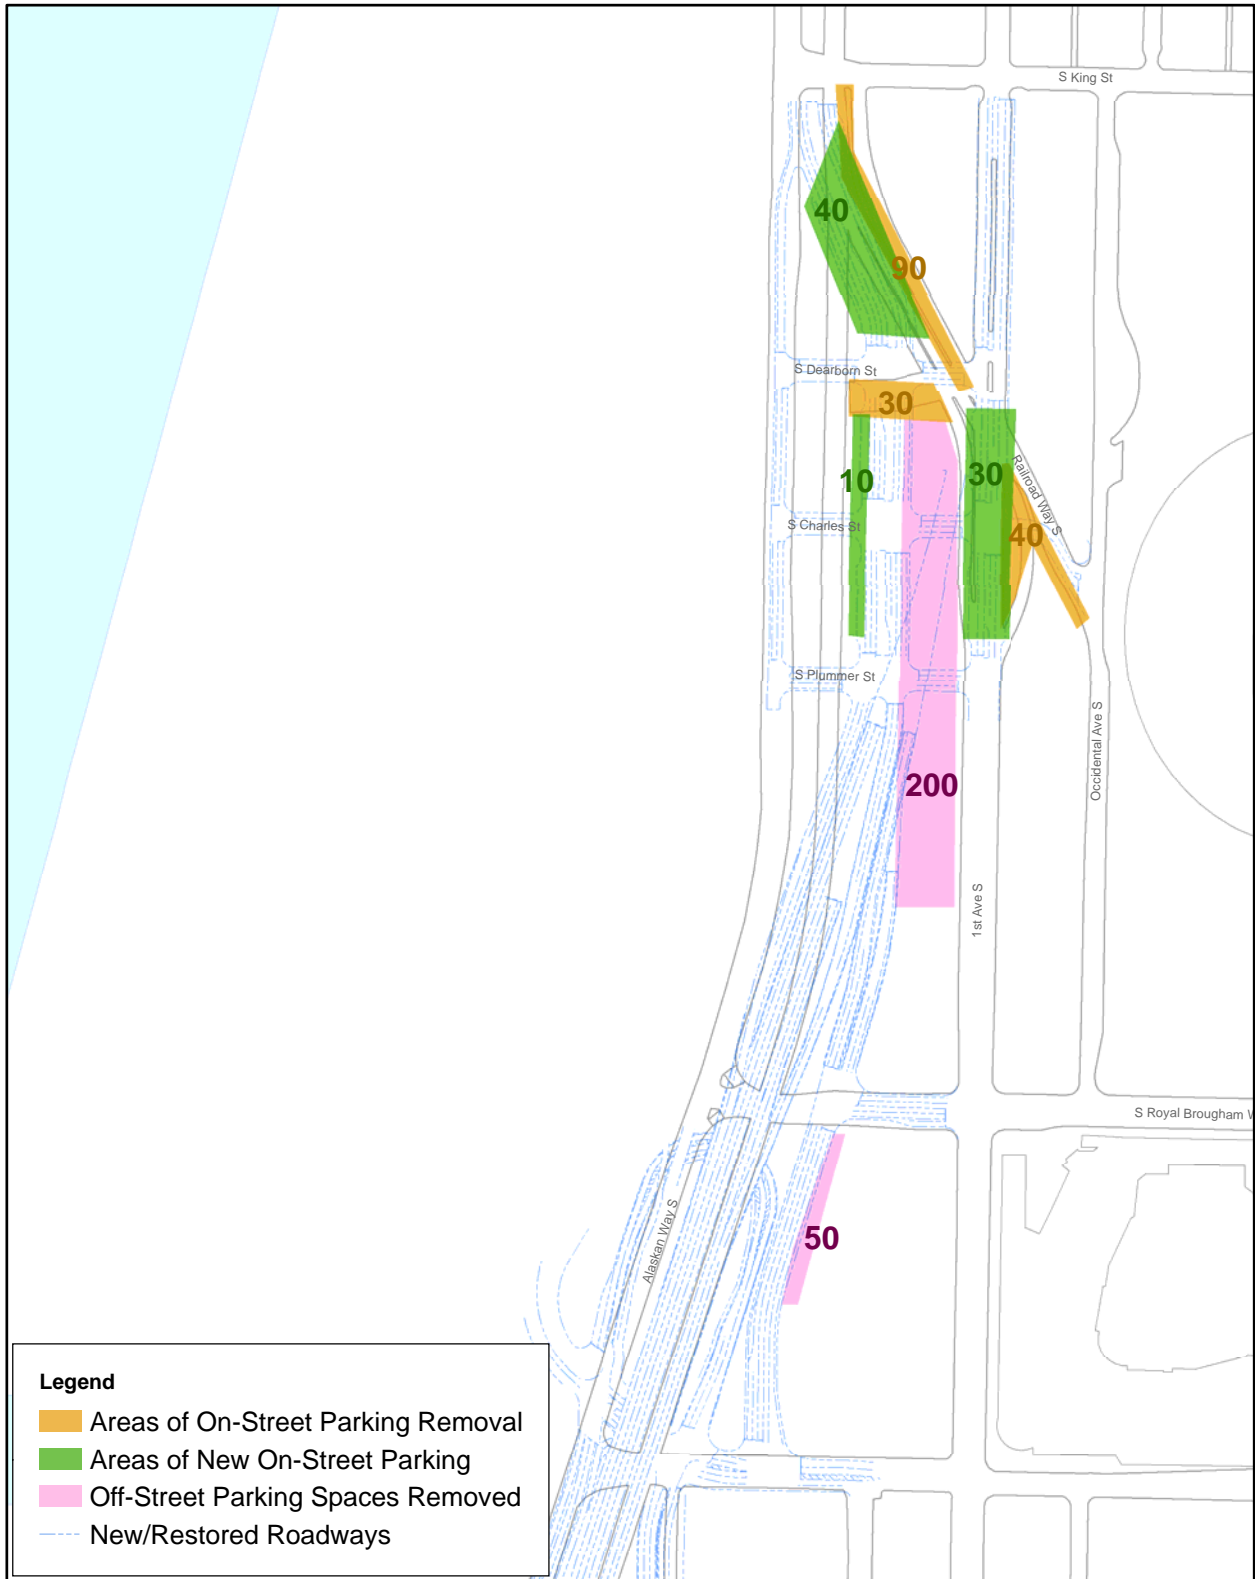

22 The south portal area encompasses the area from approximately S. Atlantic Street
 23 to S. King Street. There are currently about 210 on-street spaces in this area that
 24 are outside of the S. Holgate Street to S. King Street Viaduct Replacement Project
 25 boundaries. Of these 210 spaces, 170 are short-term and 40 are long-term spaces.
 26 The Bored Tunnel Alternative would replace approximately 130 of the on-street
 27 spaces, with an overall loss of about 80 spaces. SDOT will ultimately determine

1 how on-street parking spaces are managed and will likely encourage short-term
2 parking instead of long-term parking.

3 Approximately 250 off-street parking spaces would be permanently affected by
4 the Project. Of these spaces, about 200 are on the Washington–Oregon Shippers
5 Cooperative Association (WOSCA) property and are currently unavailable due to
6 S. Holgate Street to S. King Street Viaduct Replacement Project construction.
7 However, the S. Holgate Street to S. King Street Viaduct Replacement Project
8 assumed that these 200 spaces could be replaced. With the Bored Tunnel
9 Alternative, there may be space on the WOSCA site to replace some of the off-
10 street parking; however, the conservative assumption is that these spaces would
11 not be replaced. As a result, the 200 spaces on the WOSCA site are included as an
12 effect of the Bored Tunnel Alternative. Future use of the space will be up to
13 WSDOT or potential future property owners. Exhibit 5-42 shows the location of
14 the parking spaces affected.

15 In this area, the majority of the parking losses are off-street losses (i.e., public pay
16 lots), which are abundant and underutilized in the stadium area when events are
17 not taking place. The off-street parking utilization rate for the stadium area is
18 about 31.1 percent on an average non-event weekday (PSRC 2006). Because
19 parking lots are generally underutilized in the stadium area, parking spaces are
20 not anticipated to be difficult to find during average days.

21 During events at the stadiums, finding available parking may be more
22 challenging or may cost more than under current conditions. However, a number
23 of major parking facilities are located near the stadiums, including the Safeco
24 Field Garage, Stadium Exhibition Center Garage, Union Station Garage, North
25 Lot (Qwest Field), Impark Parking, and Home Plate Parking. These six parking
26 facilities provide about 6,900 parking spaces for use during events. Many smaller
27 parking lots and garages are also within walking distance of the stadiums. Event-
28 goers will continue to be encouraged to use bus and rail service and to carpool to
29 the stadiums. The Safeco Field Transportation Management Plan and the Qwest
30 Field Transportation Management Program both include parking reduction and
31 transit-related goals and mitigation measures that aim to reduce the number of
32 event attendees who require parking near the stadiums.

1 **5.8.2 North Portal**

2 The north portal area extends from just south of Denny Way at the Battery Street
3 Tunnel north portal along SR 99 to Roy Street and includes some surrounding streets.
4 There are approximately 70 on-street short-term parking spaces and approximately
5 230 on-street long-term spaces within the north portal project area, for a total of 300
6 on-street spaces. The on-street long-term spaces mainly consist of metered spaces with
7 a 10-hour limit. For the Bored Tunnel Alternative, approximately 80 spaces would be
8 replaced, resulting in a loss of 220 on-street spaces, compared with existing conditions.
9 Off-street parking also would be reduced, but only by approximately 40 spaces. In
10 addition, as the design progresses, changes are under consideration that may allow
11 restoration of one of the off-street parking lots, which would reduce the number off-
12 street spaces that are lost. Exhibit 5-43 shows the location of the affected parking
13 spaces in the north portal area.

14 As was the case for the south portal area, SDOT would ultimately determine how
15 on-street parking spaces are managed, so no assumptions are made about whether
16 the new and replaced on-street spaces would be long- or short-term spaces.

17 There is no difference in parking effects between Options 1 and 2.

18 **5.9 Pedestrians**

19 **Key Findings**

- 20 • Project improvements in the south, near the stadiums, include removal of
21 the Railroad Way ramps from First Avenue S., a new roadway grid, and
22 associated sidewalk facilities between S. Royal Brougham Way and
23 S. King Street, which would considerably improve pedestrian mobility
24 and accessibility in this area.
- 25 • A dedicated 25-foot-wide pedestrian and bicycle path on the east side of
26 the new Alaskan Way, an extension of the trail constructed as part of the
27 S. Holgate Street to S. King Street Viaduct Replacement Project, would
28 greatly increase the overall pedestrian experience in the stadium and
29 south waterfront areas, as well as the connectivity to the existing
30 combined pedestrian/bicycle trail to Myrtle Edwards Park and the
31 E. Marginal Way bike lanes.
- 32 • Project-related improvements north of the Battery Street Tunnel include
33 street reconnections over SR 99 at John, Thomas, and Harrison Streets,
34 with Mercer Street crossing under SR 99, and the removal and backfilling
35 of Broad Street. These improvements to reconnect the grid in the Seattle
36 Center/South Lake Union area would dramatically improve pedestrian
37 safety, access, and mobility in the area as well.

Source: City of Seattle, 2009.

**Exhibit 5-43
 North Portal Affected
 Parking Spaces**

- 1 • Option 1 for the north portal would provide better mobility and access for
2 pedestrians because it provides crosswalks on all sides of a signalized
3 intersection with Mercer Street, as well as providing an additional access
4 point to the combined bicycle and pedestrian facility on the north side of
5 Mercer Street. Option 2 would not provide a signalized crossing of
6 Mercer Street at Sixth Avenue.

7 5.9.1 Pedestrian Facilities Provided

8 2015 Baseline

9 Pedestrian facilities under Baseline conditions are very similar to those discussed
10 for existing conditions, with the exception of the pedestrian facilities added by the
11 S. Holgate Street to S. King Street Viaduct Replacement Project. The S. Holgate
12 Street to S. King Street Viaduct Replacement Project will construct combined
13 pedestrian and bicycle facilities adjacent to Terminal 46 and on the east side of the
14 new surface Alaskan Way extension, as well as improve sidewalk and crosswalk
15 facilities on S. Atlantic Street. More detail on the pedestrian facilities included in
16 the S. Holgate Street to S. King Street Viaduct Replacement Project can be found
17 in the SR 99: S. Holgate Street to S. King Street Viaduct Replacement Project
18 Environmental Assessment and Draft Section 4(f) Evaluation (FHWA and
19 WSDOT 2008). No other substantial pedestrian facilities or connections are
20 known or anticipated to be constructed by the City of Seattle within the project
21 area within this timeframe.

22 Viaduct Closed (No Build Alternative)

23 As was noted under Baseline conditions, no additional pedestrian facilities are
24 known or anticipated to be constructed by the City of Seattle within the project
25 area. However, a key difference between the existing conditions, Baseline, and
26 Viaduct Closed (No Build Alternative) is the expected increase in auto traffic on
27 surface streets through downtown Seattle. In certain instances, the increase in
28 auto traffic may result in an increase in intersection-related conflicts between
29 pedestrians and autos at intersections. This could be particularly true for
30 pedestrian crossings that occur in conflict with right-turning auto movements.

31 Bored Tunnel Alternative

32 South Portal Area

33 The Bored Tunnel Alternative would include additional pedestrian facilities on
34 the new roadway grid between First Avenue S. and E. Marginal Way. The new
35 east-west roadways of S. Plummer, S. Charles, and S. Dearborn Streets would
36 include sidewalks on all approaches of the new roadway grid, except for the
37 southern side of the Alaskan Way and S. Plummer Street intersection that services

1 the SR 99 on- and off-ramps. The sidewalks would also provide access to the
2 green space west of the SR 99 southbound on-ramp and the 14-foot-wide
3 combined pedestrian and bike trail adjacent to Port of Seattle property.

4 A new 25-foot-wide combined pedestrian/bicycle trail would provide the primary
5 north-south pedestrian facility in the southern portion of the project area. This
6 proposed trail is an extension of the trail constructed as part of the S. Holgate
7 Street to S. King Street Viaduct Replacement Project that runs adjacent to the East
8 Frontage Road. Under the Bored Tunnel Alternative, the combined pedestrian/
9 bicycle facility would continue northward on the east side of the SR 99
10 northbound off-ramp to Alaskan Way and the new street grid at S. Plummer
11 Street. The trail would remain on the east side of Alaskan Way from S. Plummer
12 Street to S. Dearborn Street and the proposed plaza immediately north of the new
13 Alaskan Way and S. Dearborn Street intersection. The trail would continue to
14 S. King Street, where it would connect to the existing combined pedestrian/bicycle
15 facility to Myrtle Edwards Park.

16 North Portal Area

17 North of the Battery Street Tunnel, pedestrian and bicycle connectivity would be
18 improved across SR 99 and across what is currently Broad Street. The Aurora
19 Avenue improvements would provide new crossings at John, Thomas, and
20 Harrison Streets over SR 99, and a widened Mercer Street would cross under
21 SR 99. In addition, Broad Street would be closed and backfilled to allow the street
22 grid to be reconnected from approximately Taylor Avenue N. to Ninth Avenue N.
23 A new Sixth Avenue N. would be provided between Harrison and Mercer Streets.

24 The new crossings at John, Thomas, and Harrison Streets would include
25 approximately 10-foot-wide sidewalks on both sides. On the north side of Mercer
26 Street there would be 25 feet for bicycle and pedestrian pathways. A sidewalk
27 would also be located along the south side of Mercer Street.

28 Option 1 provides the ability for pedestrians traveling on Sixth Avenue to connect
29 to the combined pedestrian and bicycle trail on the north side of the redesigned
30 Mercer Street. Option 2 is assumed to not allow any pedestrian crossing
31 movements at the intersection of Sixth Avenue N. and Mercer Street. Under
32 Option 2, it is expected that pedestrians would be required to cross at either Fifth
33 Avenue N. and Mercer Street or Dexter Avenue N. and Mercer Street, depending
34 on the walker's desired starting point and destination.

35 **5.9.2 SR 99 Corridor Effects on Pedestrian Mobility and Access**

36 In the southern portion of the project area, the addition of sidewalks as part of the
37 new roadway grid and the 25-foot-wide combined pedestrian/bicycle trail would

1 greatly increase pedestrian mobility and accessibility between the stadium and
2 waterfront areas, as well as connectivity to regional facilities to the north.

3 North of the Battery Street Tunnel, project improvements that would provide
4 connections across SR 99 at John, Thomas, Harrison, and Mercer Streets would
5 dramatically increase pedestrian safety and mobility across SR 99 in the Seattle
6 Center and South Lake Union areas and greatly improve the pedestrian
7 experience.

8 Of the two connection and extension options under consideration, Option 1
9 would provide better mobility and access for pedestrians because it provides
10 crosswalks on all sides of a signalized intersection, and it provides an additional
11 access point to the combined bicycle and pedestrian facility on the north side of
12 Mercer Street. Option 2 does not provide pedestrian access across Mercer Street
13 at Sixth Avenue and may require out of direction travel for pedestrians who are
14 unaware of the crossing restriction.

15 5.10 Bicycles

16 Key Findings

- 17 • Bicycle facility improvements in the project area include new, in-street
18 bike lanes on Alaskan Way, E. Marginal Way, and John Street within a
19 reconnected grid system. The provision of both dedicated bicycle facilities
20 and an improved and reconnected street grid considerably enhance
21 overall connectivity and accessibility for cyclists.
- 22 • A dedicated 25-foot-wide pedestrian and bicycle path on the east side of
23 Alaskan Way in the southern project area provides an off-street bicycle
24 facility for casual bike users, as well as an extension of the existing
25 combined pedestrian/bicycle trail in the central waterfront area and points
26 north.
- 27 • The Mercer Street undercrossing would include bicycle and pedestrian
28 pathways on the north side of the roadway. This off-street facility would
29 provide casual cyclists with considerably improved east-west mobility
30 and rider experience in the Seattle Center/South Lake Union area.
- 31 • Option 1 for the extension of Sixth Avenue N. would provide cyclists with
32 an additional access point to the combined bicycle and pedestrian facility
33 on the north side of the redesigned Mercer Street. Option 2 would not
34 provide this access.

1 **5.10.1 2015 Baseline**

2 Bicycle facilities under Baseline conditions are expected to be largely the same as
3 discussed for existing conditions, with the exception of the completion of the new
4 bicycle/pedestrian overpass connecting Uptown to the waterfront at Thomas
5 Street. No other substantial additional bicycle facilities are known or anticipated
6 to be constructed by the City of Seattle within the project area that are not being
7 completed as part of the S. Holgate Street to S. King Street Viaduct Replacement
8 Project.

9 **5.10.2 Viaduct Closed (No Build Alternative)**

10 As was noted under Baseline conditions, no substantial additional bicycle
11 facilities are known or anticipated to be constructed by the City of Seattle within
12 the project area. However, a key difference between the existing conditions,
13 Baseline, and Viaduct Closed (No Build Alternative) is the expected increase in
14 auto traffic on surface streets through downtown Seattle. Bicyclists riding in the
15 street or within marked bike lanes may face increased potential for conflicts with
16 vehicles given the higher volume of traffic.

17 **5.10.3 Bored Tunnel Alternative**

18 **South Portal Area**

19 The Bored Tunnel Alternative would include the 25-foot-wide combined
20 pedestrian/bicycle trail from S. Royal Brougham Way to S. King Street, where it
21 would connect to the existing combined bicycle/pedestrian trail to Myrtle
22 Edwards Park.

23 On-street bicycle lanes would be provided in both the north and southbound
24 directions between S. Royal Brougham Way and S. King Street. A 5-foot-wide
25 southbound bike lane would be located on the new E. Marginal Way and an
26 eastbound bike lane would be located on S. Plummer Street, allowing connection
27 to both the combined pedestrian/bicycle trail that is located east of the SR 99 ramp
28 facilities and to the 5-foot-wide northbound bike lane on Alaskan Way.

29 **North Portal Area**

30 Bicycle facilities in the northern project area include in-street bike lanes on John
31 Street, between Dexter Avenue N. and Sixth Avenue N., and bicycle and
32 pedestrian pathways on the north side of Mercer Street. In addition to the John
33 Street bike lanes and the Mercer Street bicycle and pedestrian pathways, the new
34 Harrison and Thomas Street crossings of Aurora Avenue would provide
35 additional connectivity and mobility for cyclists in the Seattle Center/South Lake
36 Union area.

1 Option 1 would provide the ability for cyclists riding on Sixth Avenue to connect
2 to the combined bicycle and pedestrian trail on the north side of the redesigned
3 Mercer Street. Option 2 would allow only right-in and right-out movements
4 to/from Sixth Avenue N. to eastbound Mercer Street. No access to the westbound
5 Mercer Street or the north side of Mercer Street and the combined pedestrian-
6 bicycle facility is assumed to be provided at Sixth Avenue with the design of
7 Option 2.

8 **5.10.4 Bicyclist Mobility and Access**

9 In the southern portion of the project area, the in-street bike lanes on Alaskan
10 Way and E. Marginal Way and the 25-foot-wide combined pedestrian/bicycle trail
11 provide additional bicycle facilities and connections in the stadium and
12 waterfront areas. These facilities would be complementary to the combined
13 pedestrian/bicycle trail that would be constructed as part of the S. Holgate Street
14 to S. King Street Viaduct Replacement Project, which is on the western boundary
15 of the project area adjacent to the Port of Seattle facilities.

16 The dedicated bike lane on John Street and the shared-use facility on Mercer
17 Street would dramatically increase bicycle connections across SR 99 and vastly
18 improve rider safety and overall experience in the Seattle Center/South Lake
19 Union.

20 Of the two SR 99 connection and Sixth Avenue N. extension options under
21 consideration, Option 1 would provide an additional access point from the south
22 to the combined bicycle and pedestrian facility on the north side of Mercer Street.

23 **5.11 Ferries**

24 Colman Dock, located on Pier 50 and 52 on Seattle's downtown waterfront, is the
25 Seattle terminus for the Washington State Ferries. The passenger-only service
26 from Vashon Island also uses Colman Dock while the service from West Seattle
27 uses Pier 55 in the central waterfront. Access to Colman Dock is provided from
28 Alaskan Way at Yesler Way, and exits are provided to Alaskan Way at Yesler
29 Way and Marion Street.

30 Travel model results and traffic analysis tools were used to determine potential
31 effects on vehicles exiting or entering Colman Dock. Signal operations for the
32 ferries were assumed to remain similar to current conditions for the future (i.e.,
33 vehicles exiting the ferries would preempt north-south traffic on Alaskan way for
34 180 seconds).

1 **Key Findings**

- 2 • Under the Viaduct Closed (No Build Alternative) scenario, volumes on
3 Alaskan Way would nearly double in the vicinity of the Seattle Ferry
4 Terminal. This would result in very poor operating conditions for vehicles
5 entering and exiting Colman Dock, especially in the peak periods.
- 6 • In peak periods for the 2015 and 2030 Bored Tunnel Alternative scenarios,
7 overall LOS at the Alaskan Way and Marion Street and Alaskan Way and
8 Yesler Way intersections would improve slightly over Baseline conditions.
9 The revised roadway with an additional lane in the northbound direction
10 (assumed with the Bored Tunnel Alternative) would slightly improve
11 traffic operations.
- 12 • As with existing ferry operations, service disruptions due to issues with
13 vessels or terminals, or demand spikes associated with peak summer
14 holiday traffic, would likely still cause some disruption to traffic
15 operations along Alaskan Way in the vicinity of Marion Street and Yesler
16 Way. Vehicles trying to enter Colman Dock may exceed the storage
17 capacity of the left-turn pocket in the current design and affect
18 northbound through traffic on Alaskan Way.

19 **5.11.1 2015 Baseline**

20 Although the delay and LOS varies some by movement, overall the intersections
21 at Alaskan Way and Marion Street and Alaskan Way and Yesler Way perform
22 well (LOS C or better) in both peak periods.

23 **5.11.2 Viaduct Closed (No Build Alternative)**

24 With the viaduct closed, surface volumes on Alaskan Way would nearly double
25 in the vicinity of the Seattle Ferry Terminal. This would result in very poor
26 operating conditions for vehicles entering and exiting Colman Dock, especially in
27 the peak periods.

28 **5.11.3 2015 and 2030 Bored Tunnel Alternative**

29 The reconfiguration of Alaskan Way would allow the intersections at Alaskan
30 Way and Marion Street and Alaskan Way and Yesler Way to continue perform
31 well (LOS C or better) in both peak periods even with the anticipated increase in
32 background traffic over that time period. As with existing ferry operations,
33 however, service disruptions due to issues with vessels or terminals or demand
34 spikes associated with peak summer holiday traffic would likely still cause some
35 disruption to traffic operations along Alaskan Way near Marion Street and Yesler
36 Way. In these instances, vehicles trying to enter Colman Dock may exceed the

1 storage capacity of the left-turn pocket in the current design and affect
2 northbound through traffic on Alaskan Way.

3 5.12 Safety

4 Safety measures to compare effects and benefits of the analysis scenarios include
5 corridor design aspects and collision history.

6 Key Findings

- 7 • Restoration of the street grid between Denny Way and Mercer Street in the
8 Bored Tunnel Alternative would provide substantially improved
9 pedestrian and bicycle access across SR 99, which is expected to
10 dramatically decrease the number of pedestrian-vehicle collisions in this
11 area (previously identified as a pedestrian accident location).
- 12 • North of the Battery Street Tunnel, the Bored Tunnel Alternative would
13 consolidate access points, eliminate current conflicting weaving
14 movements, and provide acceleration/deceleration lanes and could
15 potentially decrease collision rates on SR 99 between Denny Way and
16 Mercer Street.
- 17 • The Bored Tunnel Alternative would decommission the Battery Street
18 Tunnel and the associated northbound on-ramp and southbound off-ramp
19 (the Battery Street Tunnel ramps), eliminating a currently identified
20 collision analysis location, as well as collisions within the Battery Street
21 Tunnel.
- 22 • The Bored Tunnel Alternative would replace the current midtown ramps
23 at Seneca and Columbia Streets with new ramps in the stadium area
24 connecting to Alaskan Way at S. Plummer Street – this change would
25 eliminate collisions associated with the ramp design at Seneca and
26 Columbia Streets, which contributed to mainline queuing, merging, and
27 weaving.
- 28 • The Bored Tunnel Alternative would eliminate the identified northbound
29 collision analysis location at the southern end of the viaduct, roughly
30 between S. Massachusetts Street and S. Royal Brougham Way, through
31 improved design of the replacement roadway facility.
- 32 • The Bored Tunnel Alternative is expected to increase the total volume of
33 traffic on Alaskan Way surface street, which could increase the number of
34 conflicts between vehicles and pedestrians and cyclists.

1 **5.12.1 2015 Baseline**

2 Safety aspects of the Baseline scenario would be similar to those discussed in
3 Chapter 4, Affected Environment (existing conditions), as the SR 99 roadway
4 would remain as it is currently configured. In general, overall safe operation of
5 the facility would be expected to deteriorate due to higher future year volumes
6 and increasing congestion. Additionally, with the increasing residential,
7 commercial, and retail development occurring in South Lake Union and the area
8 immediately east of Seattle Center, the challenges associated with pedestrian
9 access north of the Battery Street Tunnel would increase.

10 **5.12.2 Viaduct Closed (No Build Alternative)**

11 Under the Viaduct Closed (No Build Alternative), operations on I-5 and
12 downtown surface streets would deteriorate considerably as drivers previously
13 using the viaduct would have to divert to these other roadway facilities. The
14 increase in volumes and related congestion on I-5 and the downtown surface
15 streets is expected to increase the likelihood of vehicular accidents, as well as the
16 potential for vehicle and pedestrian and cyclist conflicts.

17 **5.12.3 2015 Bored Tunnel Alternative**

18 Exhibits 5-44 and 5-45 highlight the updated design features for the project, which
19 are discussed in the following sections.

20 **Mainline Design Features**

21 SR 99 is currently a controlled-access facility within the project area and would
22 remain a controlled-access facility. The access points provided by the Bored
23 Tunnel Alternative would be improved through better design of the ramps, fewer
24 ramps, and fewer right-turn-on, right-turn-off access points that are associated
25 with known crash locations. These ramps and crash locations that would be
26 eliminated include the Seneca and Columbia Street ramps, the Western and Elliott
27 Avenue ramps, the Battery Street ramps at the south end of the Battery Street
28 Tunnel, and the right-on, right-off access movements from John, Thomas, and
29 Harrison Streets north of the Battery Street Tunnel.

30 The Battery Street Tunnel and associated Western and Elliott Avenue ramps and
31 the Battery Street ramps would be decommissioned, which would eliminate the
32 currently identified collision analysis location. North of the Battery Street Tunnel,
33 access to mainline SR 99 would be consolidated to single ramps, with distribution
34 to other streets occurring in the street grid. Collisions associated with the
35 existing, uncontrolled side-street connections in this area would be eliminated.
36 John, Thomas, and Harrison Streets would be reconnected, passing over lowered
37 SR 99 just north of the bored tunnel. These would provide pedestrian connections

1 between Denny Way and Mercer Street, reducing (illegal) pedestrian crossings of
 2 SR 99 that occasionally occur today.

3 The design of the Bored Tunnel Alternative would provide 12-foot-wide lanes
 4 throughout the entire length of the tunnel, providing drivers with increased room
 5 to maneuver. This may reduce erratic driver behavior that currently occurs in
 6 transition areas and locations with narrow lanes on the existing viaduct.

7 As shown in Exhibit 5-44, both inside and outside shoulder widths on the Bored
 8 Tunnel Alternative would be considerably improved over the existing viaduct,
 9 providing improved sight distance for motorists. The existing viaduct typically
 10 provides 1 foot for both inside and outside shoulder width, whereas the Bored
 11 Tunnel Alternative would provide anywhere from 2 feet to 6 feet in the majority
 12 of the tunnel, to 10 feet of shoulder width for the stadium area.

13 **Exhibit 5-44. SR 99 Mainline Design Features**

Mainline Design Features	Location	Existing Facility	Bored Tunnel Alternative
Access Control	Stadium Area	Controlled vehicle access	Controlled vehicle access
	Midtown	Controlled vehicle access	Controlled vehicle access
	North	Partially controlled (right-on, right-off) access	Partially controlled (right-on, right-off) access north of Thomas Street
Maximum Grade (up or down)	Stadium Area	5%	5%
	Midtown	4%	4%
	North	5%	5%
Lane Width	Stadium Area	12–13.5 feet	12 feet
	Midtown	9.5–13 feet	12 feet
	North	10–13 feet	12 feet
Multi-level	Stadium Area	Multi-level	Multi-level/Barrier
	Midtown	Multi-level	Multi-level
	North	Barrier	Multi-level/Barrier
Inside Shoulder Width	Stadium Area	1 foot	4 feet
	Midtown	1 foot	6 feet (SB) 2 feet (NB)
	North	1 foot	6 feet (SB) 2 feet (NB)

Exhibit 5-44. SR 99 Mainline Design Features (continued)

Mainline Design Features	Location	Existing Facility	Bored Tunnel Alternative
Outside Shoulder Width	Stadium Area	1 foot	10 feet
	Midtown	1 foot	2 feet (SB) 6 feet (NB)
	North	0 feet (sidewalks)	2 feet (SB) 6 feet (NB)
Pedestrian Accommodation	Stadium Area	Pedestrians prohibited; grade-separated crossings provided	Pedestrians prohibited; grade-separated crossings provided
	Midtown	Pedestrians prohibited; grade-separated crossings provided	Pedestrians prohibited in the tunnel
	North	Sidewalks provided on both sides; undercrossings at Broad and Mercer Streets	Pedestrians prohibited; grade-separated crossings provided

The new grade-separated crossings at John, Thomas, and Harrison Street would provide additional pedestrian crossings of SR 99, as well as the redesigned Mercer Street crossing. This reconnection of the grid is expected to considerably reduce the occurrence of collisions involving pedestrians north of the Battery Street Tunnel, a previously identified pedestrian accident location.

Ramp Design Features

As shown in Exhibit 5-45, ramp design improvements as part of the Bored Tunnel Alternative mainly address design limitations of short deceleration lengths, limited vehicle storage, and high curvature. In many instances, all three of the noted design limitations are associated with a single ramp, such as the southbound Elliott Avenue and Seneca Street off-ramps.

The Bored Tunnel Alternative would eliminate the midtown area ramps of Seneca and Columbia Streets and Western and Elliott Avenues, all of which are associated with congestion and higher rates of crashes (with the exception of the southbound Elliott Avenue on-ramp). Elimination of these ramps would improve mainline operations and address design standards on the existing facility that are less than those found on newer highway facilities.

While the Bored Tunnel Alternative does have two ramps with either a reduced merge length or a reduced speed, the design of the northbound on-ramp in the stadium area and the northbound off-ramp to Republican Street would still provide improved overall design and safe operations.

1 **Exhibit 5-45. SR 99 Ramp Design Features**

Ramp Design Features	Location	Existing Facility	Bored Tunnel Alternative
Maximum Grade (up or down)	Stadium Area	6%	5–7%
	Midtown	8%	No midtown ramps provided
	North	2–3%	5–7%
Outside Shoulder Width	Stadium Area	6 feet	8 feet
	Midtown	1 foot	No midtown ramps provided
	North	N/A	2–8 feet
Location of Merged On-Ramps (left or right side)	Stadium Area	N/A	NB On-Ramp
	Midtown	Battery Street NB On, Columbia Street SB On	None
	North	N/A	SB On-Ramp
Ramp Design Limitations (short deceleration length, limited vehicle storage at termini, or high curvature)	Stadium Area	N/A	NB on reduced merge length
	Midtown	Seneca Street NB Off, Columbia Street SB On, Western Avenue NB Off, Western Avenue NB On, Western Avenue SB Off	No midtown ramps provided
	North	Denny Way SB Off, Broad Street SB Off, Mercer Street NB Off	NB Off at Republican reduced speed

2

3 **5.12.4 2030 Project**

4 With the removal of the existing viaduct and the associated removal of the
 5 midtown ramps of Columbia and Seneca Streets and Western and Elliott
 6 Avenues, an increased number of vehicles would be accommodated on the new
 7 Alaskan Way surface street and perhaps other downtown streets. This increase in
 8 vehicles may lead to increased operational congestion, and possibly increased
 9 vehicle and pedestrian and cyclist conflicts.

10 However, these potential impacts are expected to be mitigated by traffic signal
 11 and progression improvements and associated facility design that focuses on
 12 pedestrian and cyclist safety. Facility design associated with pedestrian and
 13 cyclist mobility include a large pedestrian promenade along the proposed
 14 Alaskan Way surface street, appropriately located and well marked crosswalks,
 15 as well as bicycle lanes and sharrows within the roadway.

1 5.13 Event Traffic

2 Key Findings

- 3 • The S. Holgate Street to S. King Street Viaduct Replacement Project and
4 SR 519 Intermodal Access Project – Phase 2 would improve stadium access
5 to/from the south and east, respectively, with or without the Alaskan Way
6 Viaduct Replacement Project and Program in place. These improved
7 connections in the south end would enhance overall capacity for events by
8 providing more direct access to/from regional facilities (SR 99, I-90, I-5,
9 etc.).
- 10 • The convergence of additional traffic streams into and out of the stadium
11 area (due to new ramp connections) for the Baseline, Project, and Program
12 scenarios may require extensive traffic management measures for key
13 arterials near the stadiums prior to and following large events.
- 14 • Congestion levels would be similar for the Baseline, Project, and Program
15 scenarios. Viaduct Closed (No Build Alternative) conditions would show
16 higher levels of congestion compared to other scenarios.

17 5.13.1 South Portal Area

18 By the 2015 and 2030 horizon years, sporting and other major events at Safeco
19 Field and Qwest Field will likely continue to draw large crowds and result in high
20 concentrations of traffic movements into and out of the stadium area prior to and
21 following events. Regardless of the regional connections in place, vehicular and
22 pedestrian-related congestion associated with such events would be managed in a
23 manner similar to current practices in terms of detours, traffic control, and
24 turning movement restrictions. Event-related traffic associated with the stadium
25 facilities in the south end are discussed qualitatively below in the context of the
26 four applicable scenarios: 2015 Baseline, 2015 Viaduct Closed (No Build
27 Alternative), 2015 Project, and 2030 Project.

28 2015 Baseline

29 The roadway network in the south end for the 2015 Baseline includes two major
30 projects that precede the Alaskan Way Viaduct Replacement Project: (1) the
31 S. Holgate Street to S. King Street Viaduct Replacement Project, and (2) the SR 519
32 Intermodal Access Project – Phase 2. When these two projects are completed,
33 roadway connections in the south end to/from regional facilities such as SR 99 are
34 expected to change significantly prior to completion of the Alaskan Way Viaduct
35 Replacement Project. For example, as part of the SR 519 Phase 2 project, the
36 connection between S. Atlantic Street and I-90/I-5 would be improved to
37 accommodate more direct two-way access for stadium area traffic to/from the

1 east. Also, S. Royal Brougham Way would be converted to a local access arterial
2 with a loop ramp section connecting Third Avenue S. to S. Royal Brougham Way
3 on the east side of the BNSF rail line. For the S. Holgate Street to S. King Street
4 Viaduct Replacement Project, new ramps to/from the south on SR 99 are
5 introduced which add a new level of stadium access not previously provided
6 under current conditions.

7 With these new connections in place, traffic congestion during events would
8 likely be reduced compared to pre-Baseline conditions (i.e., without the
9 S. Holgate Street to S. King Street Viaduct Replacement Project and SR 519
10 Intermodal Access Project) due to more direct access to major roadway facilities
11 and generally higher levels of ingress and egress capacity. Improved options for
12 local traffic circulation and regional access would be provided while
13 opportunities for traffic control/management on key arterials would be
14 maintained.

15 **Viaduct Closed (No Build Alternative)**

16 Under the Viaduct Closed (No Build Alternative) scenario, traffic conditions
17 during events in the south end would be negatively affected due to the removal
18 of regional access to/from the north via SR 99. While connections to/from I-5
19 would be maintained for regional access, these routes would become more
20 congested as drivers increasingly rely on them to avoid the local street network.
21 North-south arterials in the downtown core such as First and Fourth Avenues
22 would also experience greater levels of demand and congestion as drivers use
23 these routes to continue north to communities such as Ballard and Green Lake.

24 **2015 Project**

25 While new roadway connections in the south end would be introduced by the
26 S. Holgate Street to S. King Street Viaduct Replacement Project and SR 519
27 Intermodal Access Project (as described previously), changes to the street system
28 in the stadium area would occur when the Alaskan Way Viaduct Replacement
29 Project is completed.

30 Roadway elements that are specific to the project would include the following:

- 31 • First Avenue S. ramps to/from the north (SR 99) would be removed but
32 replaced by similar connections to/from the north off of S. Royal
33 Brougham Way.
- 34 • A new surface frontage road west of First Avenue S. and east of SR 99
35 (known as the East Frontage Road) would be introduced and would
36 provide the access to/from the north.

- 1 • New intersections along First Avenue S., an extended segment of Alaskan
2 Way, and a West Frontage Road would be introduced between S. Royal
3 Brougham Way and S. King Street (creating three new east-west arterials
4 and nine new intersections).
- 5 • New ramps connecting the stadium area to/from the south on SR 99 (just
6 south of S. King Street) would be added to improve access regional access.

7 These roadway changes would likely improve circulation and reduce overall
8 congestion levels at critical intersections near the stadiums during large events by
9 providing more direct access to regional facilities such as SR 99 and I-5.
10 However, due to the reliance on First Avenue S. for access to/from the north and
11 south in the modified roadway network, congestion on First Avenue S. between
12 S. Atlantic Street and S. King Street may become more heavily concentrated for
13 short durations before and after events.

14 In any case, similar opportunities for short-term traffic management and detour
15 routing would be maintained with the new roadway network. Pedestrian
16 movements would be managed at key crossing points near the stadiums and on
17 major arterials similar to current practices.

18 2030 Project

19 Overall event-based traffic demands for 2030 Project conditions would likely be
20 higher than 2015 Project event volumes, primarily due to background increases in
21 commute and non-commute peak hour volumes by the 2030 horizon year. As
22 such, sporting and other major events at Safeco Field and Qwest Field that occur
23 near or around afternoon commute periods by 2030 would experience more
24 pronounced levels of congestion compared to 2015 conditions. However, given
25 that the roadway network would be consistent between 2015 and 2030 Project
26 conditions in terms of improved access to regional facilities, traffic management
27 practices in place for 2015 Project conditions should be reasonably effective by the
28 2030 horizon.

29 5.13.2 North Portal Area

30 As discussed in Chapter 4, Affected Environment, event traffic related to Seattle
31 Center currently relies on Mercer Street, Denny Way, Broad Street, and various
32 connections to/from SR 99 for ingress/egress prior to and following sporting
33 events, concerts, festivals, etc. As more and larger events take place at Seattle
34 Center in the future, attendance levels would generally increase and would be
35 accompanied by larger background demands on local streets and regional
36 facilities such as SR 99 and I-5.

1 No major network changes are anticipated in the north end for the Baseline
2 scenario outside of Mercer Street conversion to two-way operations east of Ninth
3 Avenue. Also, the Viaduct Closed (No Build Alternative) scenario would not
4 include any appreciable differences in network characteristics beyond existing
5 conditions other than the central waterfront viaduct section of SR 99 being
6 unavailable for use. However, substantial modifications to the local street system
7 are proposed under 2015 and 2030 Project scenarios which may improve access
8 to/from and across SR 99. Changes associated with the project elements would
9 add redundancy in the street grid and potentially reduce congestion during major
10 events.

11 Event-related traffic associated with Seattle Center is discussed qualitatively
12 below for the four applicable scenarios: 2015 Baseline, Viaduct Closed (No Build
13 Alternative), 2015 Project, and 2030 Project.

14 **2015 Baseline**

15 Under Baseline conditions the street network near Seattle Center, including
16 connections to/from SR 99, are not expected to change. However, the Mercer
17 Corridor East Project is assumed to be completed, which converts Mercer Street
18 into a two-way arterial between Fairview Avenue and Dexter Avenue. At-grade
19 connections to/from SR 99 are maintained and the northbound off-ramp to
20 Mercer/Dexter is also retained.

21 With no new connections in place to accommodate event trips, traffic congestion
22 during Seattle Center events would be similar to pre-Baseline conditions (i.e.,
23 without the Mercer Corridor East Project in place). Current (existing conditions)
24 issues related to event-based demand concentrations and capacity constraints
25 would need to be addressed but with slightly greater requirements in terms of
26 traffic control, directional signage, lane restrictions, etc. due to higher background
27 traffic levels.

28 **Viaduct Closed (No Build Alternative)**

29 Event traffic at Seattle Center for the Viaduct Closed (No Build Alternative)
30 scenario would present similar challenges as the Baseline in terms of high
31 concentrations of traffic prior to and following events. Requirements for traffic
32 control/management, directional signage, and potential lane restrictions would
33 also be similar to Baseline conditions and existing conditions.

34 **2015 Project**

35 The proposed roadway elements under the 2015 Project scenario represent
36 substantial changes to the street network near Seattle Center and areas adjacent to

1 the South Lake Union (SLU) neighborhood. Key elements associated with the
2 Alaskan Way Viaduct Replacement Project include the following:

- 3 • A new surface roadway between Sixth Avenue N. and Dexter Avenue N.
4 (along the original SR 99 alignment) known as Aurora Avenue.
- 5 • Connecting roadways across SR 99 at John, Thomas, and Harrison Streets.
- 6 • SR 99 ramps to the new Aurora Avenue roadway at Harrison Street (left-
7 side ramps).
- 8 • SR 99 ramps at Republican Street to/from the south.
- 9 • Maintain SR 99 access at Roy Street and Aloha Street.
- 10 • Two-way Mercer Street from Dexter Avenue to Fifth Avenue N. (Baseline
11 converts Mercer Street to two-way from Fairview Avenue to Ninth
12 Avenue).

13 With greater redundancy in the street network provided by the project, improved
14 opportunities for traffic distribution across a more defined grid would be
15 possible, thereby spreading traffic flow over a wider range of arterials and
16 connectors. This would result in greater potential to reduce congestion on major
17 arterials such as Mercer Street by providing alternative east-west routes and
18 better circulating event trips to/from parking garages on the periphery of Seattle
19 Center. While the capacity of Mercer Street to handle egress traffic after events
20 would be reduced to some degree with the conversion of Mercer Street to two-
21 way operations (compared to the original one-way system), the added east-west
22 connectors and access improvements to/from SR 99 should serve event traffic
23 more efficiently overall.

24 In addition, the surface Aurora Avenue configuration would allow better
25 pedestrian access to Seattle Center from SR 99/Aurora Avenue, including those
26 pedestrians who take transit.

27 2030 Project

28 Similar to the south end, peak hour commute and non-commute volumes by the
29 2030 horizon year would be higher compared to 2015 background traffic levels.
30 As such, events at Seattle Center by 2030, especially during afternoon commute
31 periods, would experience more pronounced levels of congestion. However,
32 given the added network redundancy provided by the project elements (as
33 described in the 2015 Project discussion), event-related traffic congestion levels
34 for 2030 Project conditions would likely be lower than without the project
35 elements in place.

1 5.14 Potential Tolling Effects

2 The operational benefits and impacts of tolling for the bored tunnel facility will be
3 investigated as part of a larger tolling study for the Program. Specific toll-based
4 travel demand models are being developed and refined to assess potential levels
5 of diversion that may occur due to various toll rates and user costs. This work
6 will feed into the financial analysis for the Program with the intent of determining
7 potential levels of alternative funding. The results of the diversion analysis will
8 be used to assess possible impacts on non-SR 99 facilities and provide insight as
9 to what traffic-related mitigation measures (if any) may be needed to minimize or
10 address the impacts of tolling on the larger street network. See Appendix S,
11 Tolling Report for more information.

12 5.15 Operational Mitigation

13 Long-term (post-construction) transportation mitigation measures are not
14 anticipated for the project.

15 5.16 Operational Benefits

16 Operational benefits of the Bored Tunnel Alternative can be seen both in
17 comparison to the 2015 Baseline scenario as well as the Viaduct Closed (No Build
18 Alternative). The Baseline itself would have improved access in the south end
19 area in comparison to existing conditions with the addition of the stadium area
20 ramps to/from the south. The Viaduct Closed (No Build Alternative), however,
21 would substantially reduce mobility throughout the corridor and result in highly
22 congested conditions along Alaskan Way surface street as well as downtown
23 arterials. Travel times between Woodland Park and S. Spokane Street for the PM
24 peak hour would be expected to triple compared to the Baseline. I-5 also would
25 be expected to have increased congestion with the Viaduct Closed (No Build
26 Alternative).

27 The Bored Tunnel Alternative is projected to experience some decrease in
28 performance in overall conditions compared to the Baseline, but conditions
29 would be substantially better than the Viaduct Closed (No Build Alternative).
30 SR 99 through traffic is expected to operate better than Baseline due to the
31 removal of the merging and weaving conflicts associated with the Elliott/Western
32 ramps and the midtown ramps.

33 Peak hour travel times for SR 99 through trips are projected to be 9 to 25 percent
34 faster than under Baseline depending on the peak hour and direction, and three
35 times as fast as for the Viaduct Closed (No Build Alternative). Regarding other
36 key peak hour travel time routes analyzed, the Bored Tunnel Alternative is
37 projected to be about 1 minute slower than the Baseline between West Seattle and

1 downtown Seattle due to the removal of the midtown ramps. Between Ballard
2 and S. Spokane Street, the Bored Tunnel Alternative using the surface Alaskan
3 Way route is expected to be 2 to 8 minutes slower than Baseline, which includes
4 the existing Elliott/Western ramps. The Bored Tunnel Alternative's travel times
5 along this route would be compromised due to the lack of a connection from
6 Elliott/Western Avenues to the waterfront, causing traffic to use Broad Street,
7 which includes an at-grade rail crossing. However, using Mercer Street and the
8 bored tunnel, the Bored Tunnel Alternative is expected to be only 1 to 2 minutes
9 slower in the AM peak hour, and in the PM peak hour less than a minute slower
10 southbound, and a minute faster northbound.

11 Other benefits of the Bored Tunnel Alternative include the following:

- 12 • Improved mobility in the South Lake Union area due to the connection of
13 three east/west streets across SR 99.
- 14 • Improved access from Mercer Street to southbound SR 99 as a result of the
15 extension of Sixth Avenue N. to Mercer Street (access from westbound
16 Mercer Street would be more direct with Option 1 than Option 2).
- 17 • The Sixth Avenue Extension would also provide a new connection
18 between downtown and Uptown (the northbound to westbound
19 connection would be more direct with Option 1).

20 Areas where the Bored Tunnel Alternative is expected to cause a decrease in
21 performance as compared to the Baseline include the following:

- 22 • Alaskan Way is projected to experience 24 to 37 percent heavier traffic
23 than Baseline, but still 24 to 39 percent less than with the Viaduct Closed
24 (No Build Alternative).
- 25 • Traffic volumes would be heavier on First Avenue through Pioneer Square
26 in comparison to the Baseline.

27 Concerning the two options for the Sixth Avenue Extension, Option 1 would
28 provide more overall transportation benefit, including the following:

- 29 • Option 1 would provide all movements at Sixth Avenue and Mercer
30 Street, whereas Option 2 would allow only right turns into and out of
31 Sixth Avenue from/to Mercer Street.
- 32 • Option 1 would provide an additional route from downtown to Uptown,
33 and from I-5 via westbound Mercer Street to SR 99 southbound (Option 2
34 would provide these movements indirectly).
- 35 • Option 1 would provide a pedestrian and bike crossing of Mercer Street at
36 Sixth Avenue connecting to the proposed trail along the north side of
37 Mercer Street.

Chapter 6

6.1 Construction Effects

Given the dynamic nature of construction activities, transportation effects would vary depending on the construction period. Generally, the most disruptive travel effects (i.e., substantial sustained effects) would occur during Traffic Stages 6 and 7, when SR 99's capacity would be reduced to the greatest extent and construction activities would also affect nearby surface roadways. This chapter summarizes how conditions may vary during construction. The assumed traffic stages are described below.

6.1.1 Construction Durations

The Bored Tunnel Alternative would require about 70 months of construction. This can be broken down into eight traffic stages, starting with utility work and early construction activities prior to construction of the south portal.

The following text describes the current planning for a likely construction sequence for the project elements along with the approximate construction durations. These durations have been developed as estimates based upon what is known about the design of the project at this early stage.

Traffic Stage 1

Traffic Stage 1 would last approximately 5 months, roughly from April through August 2011. Significant construction activities are shown in Exhibit 6-1. As part of the traffic patterns established by the S. Holgate Street to S. King Street Viaduct Replacement Project, mainline SR 99 would be open from S. Holgate Street to Denny Way, and Alaskan Way surface street would have a detour route between S. King Street and S. Royal Brougham Way.

Exhibit 6-1. Traffic Stage 1 Construction Activities and Approximate Durations

Primary Construction Activity	Approximate Duration (5 months)
Begin ground improvements and relocate existing utilities	2 months
Begin installing secant piles along First Avenue – S. King Street to WOSCA site	5 months (continues in Stages 2, 3)
Initiate the design and procurement of the tunnel boring machine	5 months (18 months total – continues through Stages 2, 3, 4)
Excavate and install secant piles – WOSCA site	5 months (continues in Stage 2)

1 First Avenue S. would be reduced to one lane each way between S. King Street
2 and the WOSCA site (just north of S. Royal Brougham Way). These traffic
3 modifications would also allow for shoring improvements at the WOSCA site
4 scheduled to occur during Traffic Stage 1. In the north portal area, the Denny
5 Way ramps would remain open.

6 Traffic Stage 1 Traffic Revisions – SR 99

7 For the 5 months of Traffic Stage 1, northbound and southbound traffic would not
8 change on the existing SR 99: three lanes would be open in each direction (four
9 lanes northbound between the First Avenue S. on-ramp and the Seneca Street off-
10 ramp).

11 Traffic Stage 1 Traffic Revisions – Surface Streets

12 Traffic revisions in the south portal area include the following:

- 13 • First Avenue S. would be reduced to one lane in each direction from April
14 through August 2011. No other surface street traffic revisions would be
15 required in Traffic Stage 1. Since First Avenue S. would remain open
16 (although at reduced capacity), no detour routes are being specified at this
17 time. Traffic, however, would likely redistribute itself to parallel north-
18 south streets to avoid increased congestion associated with lane closures.

19 **Traffic Stage 2**

20 Traffic Stage 2 would last approximately 3 months, from August to November
21 2011. Primary construction activities are shown in Exhibit 6-2. As part of the
22 S. Holgate Street to S. King Street Viaduct Replacement Project, the SR 99
23 mainline northbound on-ramp and southbound off-ramp at Railroad Way to and
24 from First Avenue S. would be moved to newly constructed transitional ramp
25 structures that would allow access to the area via S. Royal Brougham Way.
26 Alaskan Way would continue to operate on the detour route between S. King
27 Street and S. Royal Brougham Way.

28 In the Bored Tunnel Alternative Traffic Stage 2, First Avenue S. would be
29 restricted to one lane in each direction between Railroad Way S. and S. Royal
30 Brougham Way. In the north end, the Denny Way ramps would remain open,
31 although Denny Way itself, along with John, Thomas, and Harrison Streets,
32 would experience lane closures due to utility relocations. Sixth Avenue would
33 also have restricted use due to modifications for utility relocations and some
34 reconfiguration of Sixth Avenue.

1 **Exhibit 6-2. Traffic Stage 2 Construction Activities and Approximate Durations**

Primary Construction Activity	Approximate Duration (3 months)
Install secant piles on First Avenue - S. King Street to WOSCA site	2-3 months (continues in Stage 3)
Demolish Railroad Way ramps	2 months
Excavate within WOSCA site and set up staging	2 months
Build and set up tunnel boring machine substation	3 months (continues in Stages 3, 4)
Excavate (12' down) & suspend utilities on First Avenue – S. King Street to Railroad Way S.	1 month (continues in Stage 3)
North Portal: Relocate utilities on Denny Way; John, Thomas, and Harrison Streets, and Sixth Avenue N.; and widen Mercer Street	3 months (continues in Stages 3, 4, 5, 6)

2 Traffic Stage 2 Traffic Revisions – SR 99

- 3 • The northbound on-ramp and southbound off-ramp would be rerouted to
 4 new transition structures accessed via S. Royal Brougham Way.
 5 • The Denny Way ramps would remain open.

6 Traffic Stage 2 Traffic Revisions – Surface Streets

7 Traffic revisions in the south portal area include the following:

- 8 • First Avenue S. would be restricted to one lane in each direction between
 9 Railroad Way S. and S. Royal Brougham Way.

10 Traffic revisions in the north portal area include the following:

- 11 • In the north end, although the Denny Way ramps would remain open,
 12 Denny Way itself, along with John, Thomas, and Harrison Streets, would
 13 experience lane closures due to utility relocations. Sixth Avenue would
 14 also have restricted use due to modifications for utility relocations and
 15 some reconfiguration of Sixth Avenue.

16 **Traffic Stage 3**

17 Traffic Stage 3 would last approximately 5 months, from November 2011 to April
 18 2012. Primary construction activities are shown in Exhibit 6-3. As part of the
 19 S. Holgate Street to S. King Street Viaduct Replacement Project, northbound
 20 traffic on SR 99 would continue to operate on the existing viaduct structure.
 21 Southbound traffic would operate on the new west mainline structure. The new
 22 northbound on-ramp and southbound off-ramp in the vicinity of S. Royal
 23 Brougham Way would continue to use the transition structures. Alaskan Way

1 would continue to operate on the detour route between S. King Street and
 2 S. Royal Brougham Way.

3 **Exhibit 6-3. Traffic Stage 3 Construction Activities and Approximate Durations**

Primary Construction Activity	Approximate Duration (5 Months)
Install secant piles on First Avenue – S. King Street to WOSCA site	2 months
Excavate/remove tiebacks, backfill with CDF on First Avenue – S. King Street to WOSCA site	1 month (continues in Stages 4, 5)
Make ground improvements along First Avenue, including excavation (12' down), utility suspension, and shoring excavation – S. King Street to WOSCA site	5 months
Bored Tunnel: Set up staging area	5 months (continues in Stage 4)
North Portal: Relocate utilities on Denny Way; John, Thomas, & Harrison Streets; and Sixth Avenue N.	5 months (continues in Stages 4, 5, 6)
Construct SR 99 detour	1 month (continues in Stages 4, 5, 6)
Build and set up tunnel boring machine substation	5 months (continues in Stage 4)

4 Traffic Stage 3 Traffic Revisions – SR 99

- 5 • In the north end, as in Traffic Stage 2, the Denny Way ramps would
 6 remain open.

7 Traffic Stage 3 Traffic Revisions – Surface Streets

8 Traffic revisions near the south portal of the bored tunnel include the following:

- 9 • First Avenue S. between S. King Street and the WOSCA site would be
 10 reduced to one lane in each direction.

11 Traffic revisions near the north portal of the bored tunnel include the following:

- 12 • Denny Way, along with John, Thomas, and Harrison Streets, would
 13 experience lane closures due to utility relocations.
 14 • Sixth Avenue would have restricted use due to modifications for utility
 15 relocations and some reconfiguration of Sixth Avenue.

16 **Traffic Stage 4**

17 Traffic Stage 4 would last approximately 4 months, from April to August 2012.
 18 Primary construction activities are shown in Exhibit 6-4. As part of the S. Holgate
 19 Street to S. King Street Viaduct Replacement Project, both northbound and
 20 southbound traffic on SR 99 would be shifted to the new west mainline structure.

1 The new northbound on-ramp and southbound off-ramp near S. Royal Brougham
 2 Way would continue to use the transition structures. Alaskan Way would
 3 continue to operate on the detour route between S. King Street and S. Royal
 4 Brougham Way.

5 **Exhibit 6-4. Traffic Stage 4 Construction Activities and Approximate Durations**

Primary Construction Activity	Approximate Duration (4 Months)
Design & procure tunnel boring machine	4 months (started in Stage 1)
Excavate/remove tiebacks, backfill with CDF on First Avenue – S. King Street to WOSCA site	4 months (continues in Stage 5)
Build and set up tunnel boring machine substation	4 months
Construct SR 99 detour	4 months (continues in Stages 5, 6)
Bored Tunnel: Set up staging areas	4 months
North Portal: Relocate utilities on Denny Way; John, Thomas, & Harrison Streets; and Sixth Avenue N.	4 months (continues in Stages 5, 6)

6 Traffic Stage 4 Traffic Revisions – SR 99

- 7
- The Denny Way ramps would remain open.

8 Traffic Stage 4 Traffic Revisions – Surface Streets

9 Traffic revisions near the south portal of the bored tunnel include the following:

- 10
- Alaskan Way S. traffic would remain reduced to one lane in each
 11 direction, northbound and southbound.

12 Traffic revisions near the north portal of the bored tunnel include the following:

- 13
- Denny Way, along with John, Thomas, and Harrison Streets, would
 14 experience lane closures due to utility relocations.
 - Sixth Avenue would have restricted use due to modifications for utility
 15 relocations and some reconfiguration of Sixth Avenue.
 - First Avenue S. between S. King Street and the WOSCA site would
 16 continue to be reduced to one lane in each direction from April to June
 17 2012. Temporary decking on the roadway surface would be in place on
 18 First Avenue S. in the same location between June and August 2012.
 19
 20

21 **Traffic Stage 5**

22 Traffic Stage 5 would last approximately 7 months, from August 2012 to March
 23 2013. Primary construction activities are shown in Exhibit 6-5. As part of the
 24 S. Holgate Street to S. King Street Viaduct Replacement Project, both northbound
 25 and southbound traffic on SR 99 would be shifted to the new west mainline

1 structure. The new northbound on-ramp and southbound off-ramp near S. Royal
 2 Brougham Way would continue to use the transition structures. Alaskan Way
 3 would continue to operate on the detour route between S. King Street and
 4 S. Royal Brougham Way.

5 **Exhibit 6-5. Traffic Stage 5 Construction Activities and Approximate Durations**

Primary Construction Activity	Approximate Duration (7 Months)
Excavate/remove tiebacks, backfill with CDF on First Avenue – S. King Street to WOSCA site	2 months
Construct SR 99 detour	7 months
Assemble tunnel boring machine	2 months
Drive tunnel boring machine	5 months (Continues in Stages 6, 7)

6 Traffic Stage 5 Traffic Revisions – SR 99

- 7 • The Denny Way ramps would remain open.

8 Traffic Stage 5 Traffic Revisions – Surface Streets

9 Traffic revisions near the north portal of the bored tunnel include the following:

- 10 • Denny Way, along with John, Thomas, and Harrison Streets, would
 11 experience lane closures due to utility relocations.
 12 • Sixth Avenue would have restricted use due to modifications for utility
 13 relocations and some reconfiguration of Sixth Avenue.
 14 • First Avenue S. between S. King Street and the WOSCA site would remain
 15 open for north-south traffic on a temporary decking roadway surface.

16 **Traffic Stage 6**

17 Traffic Stage 6 would last approximately 1 month, from March 2013 to April 2013.
 18 Primary construction activities are shown in Exhibit 6-6. During this stage the
 19 SR 99 mainline northbound and southbound would be closed at the north portal
 20 of the Battery Street Tunnel to allow for the transition to the detour roadway in
 21 the north end. However, the Elliott/Western ramps and midtown ramps would
 22 still be in operation. Alaskan Way would continue to operate on the detour route
 23 between S. King Street and S. Royal Brougham Way.

1 **Exhibit 6-6. Traffic Stage 6 Construction Activities and Approximate Durations**

Primary Construction Activity	Approximate Duration (1 Month)
Close SR 99 in both directions (northbound and southbound) at the Battery Street Tunnel north portal	1 month
Drive tunnel boring machine	1 month (continues in Stage 7)
North Access: Tie-in detour to SR 99	1 month

2 Traffic Stage 6 Traffic Revisions – SR 99

- 3 • The Denny Way southbound off-ramp would be closed (northbound on-
- 4 ramp could remain open).
- 5 • The Denny Way northbound on-ramp could remain open or traffic could
- 6 detour using Dexter Avenue to Roy Street to northbound SR 99.
- 7 • A new connection replacing the closure of the southbound SR 99 off-ramp
- 8 to Denny Way would be provided, tying into Sixth Avenue near
- 9 Republican Street.

10 Traffic Stage 6 Traffic Revisions – Surface Streets

11 Traffic revisions near the south portal of the bored tunnel include the following:

- 12 • The Alaskan Way detour from S. King Street to S. Royal Brougham would
- 13 be in operation.
- 14 • First Avenue S. between S. King Street and the WOSCA site would remain
- 15 open for north-south traffic on a temporary decking roadway surface.

16 Traffic revisions near the north portal of the bored tunnel include the following:

- 17 • Denny Way, along with John, Thomas, and Harrison Streets, would be
- 18 open.

19 **Traffic Stage 7**

20 Traffic Stage 7 would last approximately 33 months, from April 2013 to late
 21 December 2015. Primary construction activities are shown in Exhibit 6-7. As part
 22 of the S. Holgate Street to S. King Street Viaduct Replacement Project, both
 23 northbound and southbound traffic on SR 99 would be shifted to the new west
 24 mainline structure. The new northbound on-ramp and southbound off-ramp
 25 near S. Royal Brougham Way would continue to use the transition structures.
 26 Alaskan Way would continue to operate on the detour route between S. King
 27 Street and S. Royal Brougham Way.

1 **Exhibit 6-7. Traffic Stage 7 Construction Activities and Approximate Durations**

Primary Construction Activity	Approximate Duration (33 Months)
Bored Tunnel: Drive tunnel boring machine, install interior concrete & interior systems work, systems commissioning	33 months
South Portal: Construct vent building	12 months
South Portal: Construct cut-and-cover tunnel connection	12 months
Excavate tunnel boring machine recovery shaft	6 months
North Portal: Construct vent building	12 months
North Portal: Construct cut-and-cover tunnel connection	15 months
Install interior systems – electrical, mechanical, fire, and life safety	18 months
Extract tunnel boring machine	1 month

2 Traffic Stage 7 Traffic Revisions – SR 99

- 3
- 4
- 5
- 6
- 7
- 8
- 9
- 10
- 11
- 12
- 13
- 14
- 15
- 16
- 17
- Between Mercer Street and the north portal area, SR 99 would be limited to two lanes in each direction. The speed would be reduced to 40 mph, as required with the curves associated with the shifting of the roadway to the west to accommodate construction in the existing SR 99 right-of-way.
 - Denny Way southbound off- and northbound on-ramps would be closed.
 - Since the Denny Way ramps would be closed, access to that area would be provided by a new southbound connection from the realigned SR 99 to Sixth Avenue; this connection would be placed somewhere between Republican Street and Thomas Street.
 - Northbound access to SR 99 would be provided by an on-ramp from approximately the Republican Street alignment. This would join SR 99 as an add-lane.
 - No northbound egress from SR 99 would be allowed south of Roy Street.
 - Access to/from SR 99 would not be allowed from John, Thomas, or Harrison Streets.

18 Traffic Stage 7 Traffic Revisions – Surface Streets

19 Traffic revisions near the south portal of the bored tunnel include the following:

- 20
- 21
- 22
- 23
- Alaskan Way would be rerouted to the East Frontage Road from S. King Street to S. Royal Brougham Way, with two lanes in each direction.
 - First Avenue S. between S. King Street and the WOSCA site would be open for north-south traffic on a temporary decking roadway surface.

- 1 Traffic revisions near the north portal of the bored tunnel include the following:
- 2 • Denny Way, along with John, Thomas, and Harrison Streets, would be
 - 3 open (but would not connect to SR 99).
 - 4 • During this stage a connection would be made from southbound SR 99 to
 - 5 Sixth Avenue to replace the (closed) southbound SR 99 off-ramp to Denny
 - 6 Way.
 - 7 • Sixth Avenue would also be converted from one-way to two-way
 - 8 operations between Denny Way and Wall Street.

9 **Traffic Stage 8**

10 Traffic Stage 8 would last approximately 12 months, as shown in Exhibit 6-8.

11 **Exhibit 6-8. Traffic Stage 8 Construction Activities and Approximate Durations**

Primary Construction Activity	Approximate Duration (12 Months)
Demolish and remove existing viaduct	9 months
South Portal Area: Restore surface streets	12 months
North Portal Area: Restore surface streets	12 months
Decommission Battery Street Tunnel	9 to 12 months

12 Traffic Stage 8 Traffic Revisions – SR 99

- 13 • The SR 99 mainline would be open and using the newly constructed bored
- 14 tunnel.

15 Traffic Stage 8 Traffic Revisions – Surface Streets

16 Traffic revisions near the south portal of the bored tunnel include the following:

- 17 • Alaskan Way would be reduced in width between S. King Street and Pike
- 18 Street to allow for the demolition and removal of the viaduct structure.
- 19 Demolition would occur two blocks at a time, with the middle cross-street
- 20 being closed for approximately 2 weeks in duration.
- 21 • Drivers on First Avenue S. would experience lane closures necessary for
- 22 street restoration. Additionally, between Railroad Way S. and S. Royal
- 23 Brougham Way, traffic would be reduced to one lane in each direction.
- 24 • Alaskan Way would continue to be rerouted to the east as in Traffic
- 25 Stage 7.
- 26 • The Battery Street Tunnel would be decommissioned.

27 Traffic revisions near the north portal of the bored tunnel include the following:

- 1 • The new left-hand ramps to/from Harrison Street and Aurora Avenue
2 (providing connections to Denny Way) would be operational, although on
3 Denny Way and on John, Thomas, and Harrison Streets, lanes would be
4 restricted to support utility relocation. Sixth Avenue would also be
5 affected.

6 6.1.2 Proposed Detours

7 Throughout the construction of the bored tunnel and associated facilities, a
8 number of traffic detours would occur during different stages. Some of the
9 detours, such as those associated with short-duration closures of cross streets
10 during the demolition of the SR 99 viaduct, would be determined during the
11 construction phase. Other proposed detours are more substantial. Below are
12 descriptions of these detours for Traffic Stage 7, the stage considered to be
13 substantially disruptive for the longest period of time.

14 Near the north portal area, the closure of the southbound SR 99 ramp to Denny
15 Way requires a detour, as the existing street network would not be able to
16 accommodate the closure of this ramp without a replacement connection. To
17 mitigate the impacts of the closure of the southbound SR 99 Denny Way off-ramp,
18 a new connection would be constructed from southbound SR 99 (which would be
19 temporarily shifted to the west and reduced to two lanes in each direction as part
20 of the construction process) to Sixth Avenue, somewhere between Republican
21 Street and John Street.

22 Closure of the Railroad Avenue ramps that provide access between SR 99 and
23 First Avenue S. would also require a substantial detour. To maintain access to
24 and from the stadium area, a northbound on-ramp to and southbound off-ramp
25 from SR 99 would be constructed to provide access to the area via S. Royal
26 Brougham Way.

27 In addition to the detours described above, as part of the project Alaskan Way
28 from S. King Street to the WOSCA property would be rerouted to a new
29 alignment just east of SR 99.

30 6.1.3 Traffic Congestion on SR 99

31 Traffic impacts would likely be most severe during Traffic Stage 6 when SR 99 is
32 closed in both directions at the Battery Street Tunnel north portal. Traffic Stage 6,
33 however, only lasts for 1 month. This section provides a qualitative discussion of
34 anticipated congestion levels on SR 99 through the project area for the
35 construction period primarily defined by Traffic Stage 7. The primary measures
36 for mainline SR 99 performance are average speeds and travel times for
37 representative trips. Vehicle delays on SR 99 during this 33-month (estimated)

1 construction period would be expected to increase somewhat compared to
2 baseline conditions. The decreases in speeds and increases in travel times would
3 be heavily influenced by temporary changes to the SR 99 configuration in the
4 north and south, which are expected to reduce mainline capacity. Refer to
5 Exhibits 6-9 and 6-10 for diagrams of the roadway configuration during Traffic
6 Stage 7.

7 As described in the construction staging summary, northbound and southbound
8 SR 99 under Traffic Stage 7 would be reduced to two lanes between
9 approximately Columbia Street and the stadium area. The stadium area
10 southbound off-ramp would also be moved from the current left-side off-ramp to
11 First Avenue S., to a right-side off-ramp to S. Atlantic Street. Additionally, due to
12 the narrowing to two lanes prior to Columbia Street, the Columbia Street
13 southbound on-ramp would be provided with an acceleration lane for merging
14 traffic. The combination of the merge lane addition plus moving the stadium area
15 ramp to the right side eliminates one of the areas of major conflict in the facility
16 today and would likely offset some of the impacts caused by the overall capacity
17 reduction. In the north during Traffic Stage 7, SR 99 would be shifted to the west
18 to provide room for construction activities. As a result of the realignment, design
19 speeds would be reduced to 40 mph. Additionally, the current access to/from
20 Denny Way would be detoured as outlined above.

21 Travel Speeds

22 On SR 99 in the project area between S. Atlantic Street and Mercer Street, travel
23 speeds in both directions are expected to be very similar to Baseline conditions.
24 Although it is not possible to compare identical segments due to the closure and
25 relocation of some ramps during construction, it is possible to report general
26 patterns.

27 For the PM peak hour, the SR 99 mainline northbound segments are expected to
28 generally operate at speeds similar to those in the 2015 Baseline scenario north of
29 the Seneca Street off-ramp, about 30 to 34 mph. South of the Seneca Street off-
30 ramp, the northbound traffic would operate about 8 mph slower than during 2015
31 Baseline conditions, due to the restricted capacity on SR 99 that begins in the
32 stadium area. In the southbound direction, a comparison of travel speeds
33 between Traffic Stage 7 and the 2015 Baseline indicates similar speed patterns,
34 with overall speeds only slightly slower than under Baseline conditions. The
35 addition of a merge lane for the Columbia Street on-ramp in combination with
36 relocating the stadium area off-ramp to the right side is expected to help offset the
37 speed impacts of the capacity reduction in this area.

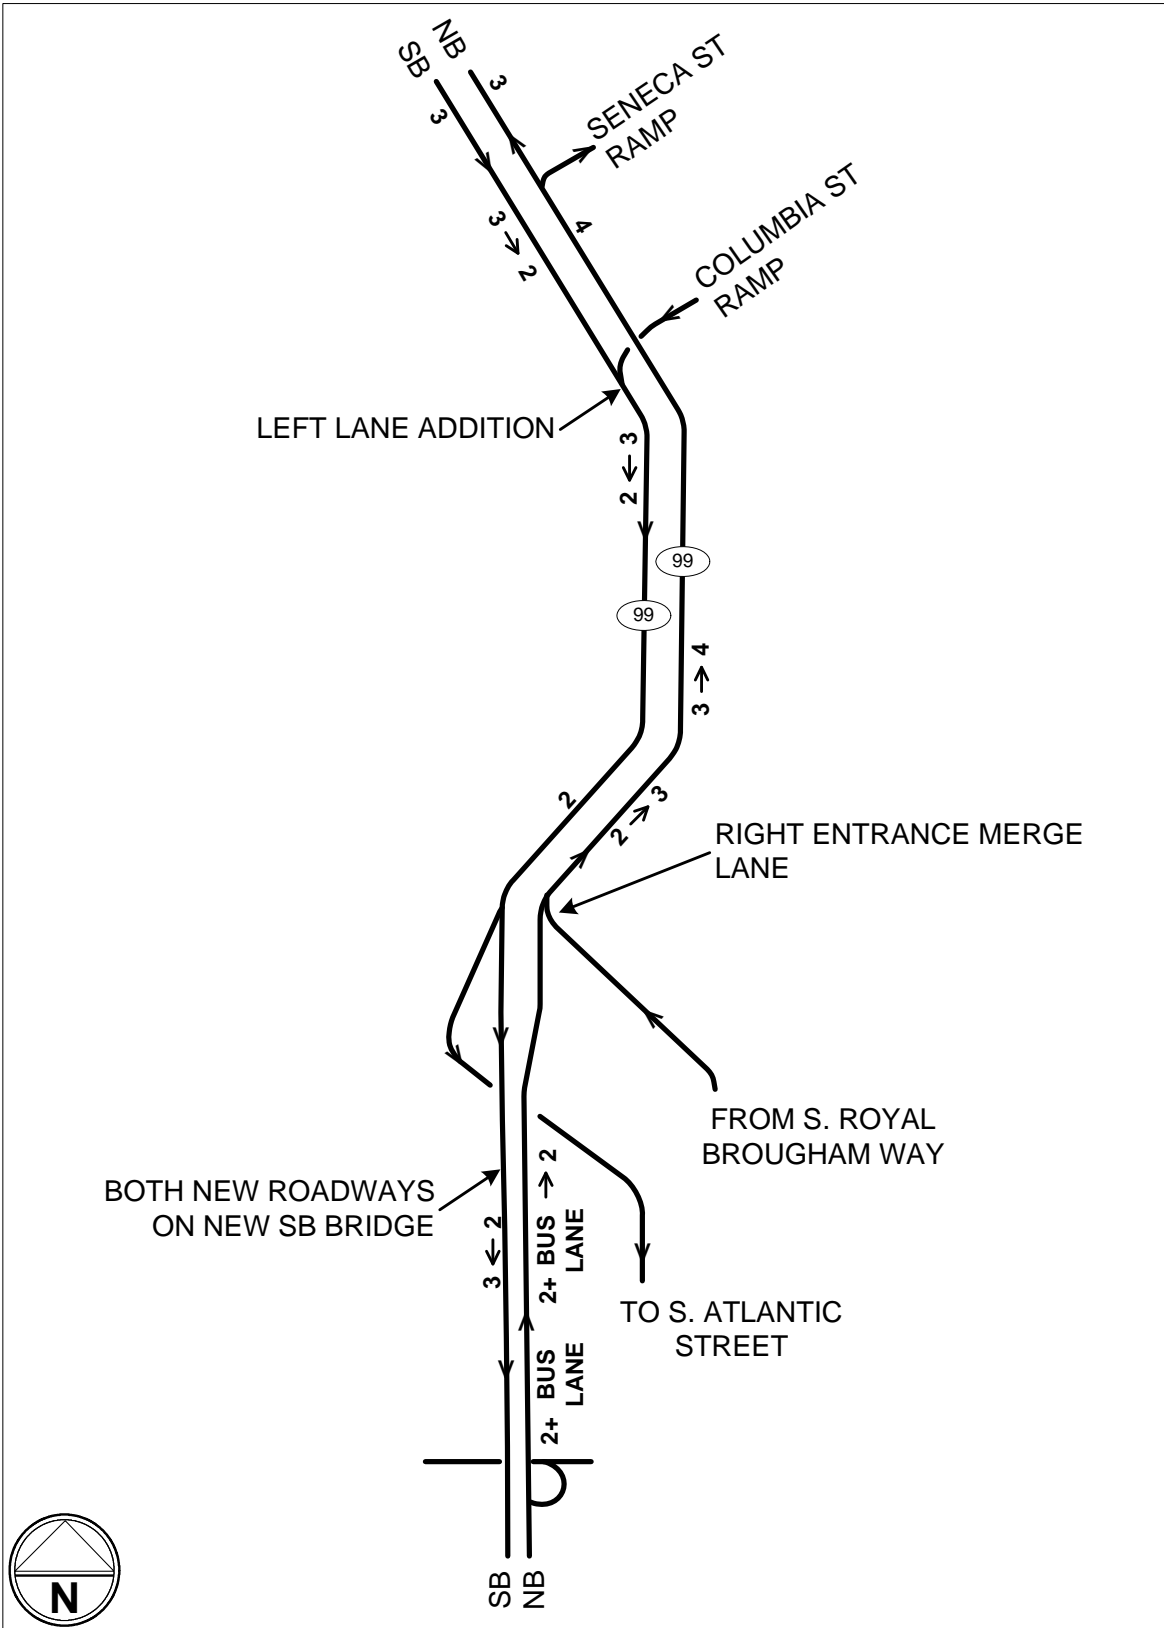

Exhibit 6-9
Roadway Configuration during
Traffic Stage 7 - South End

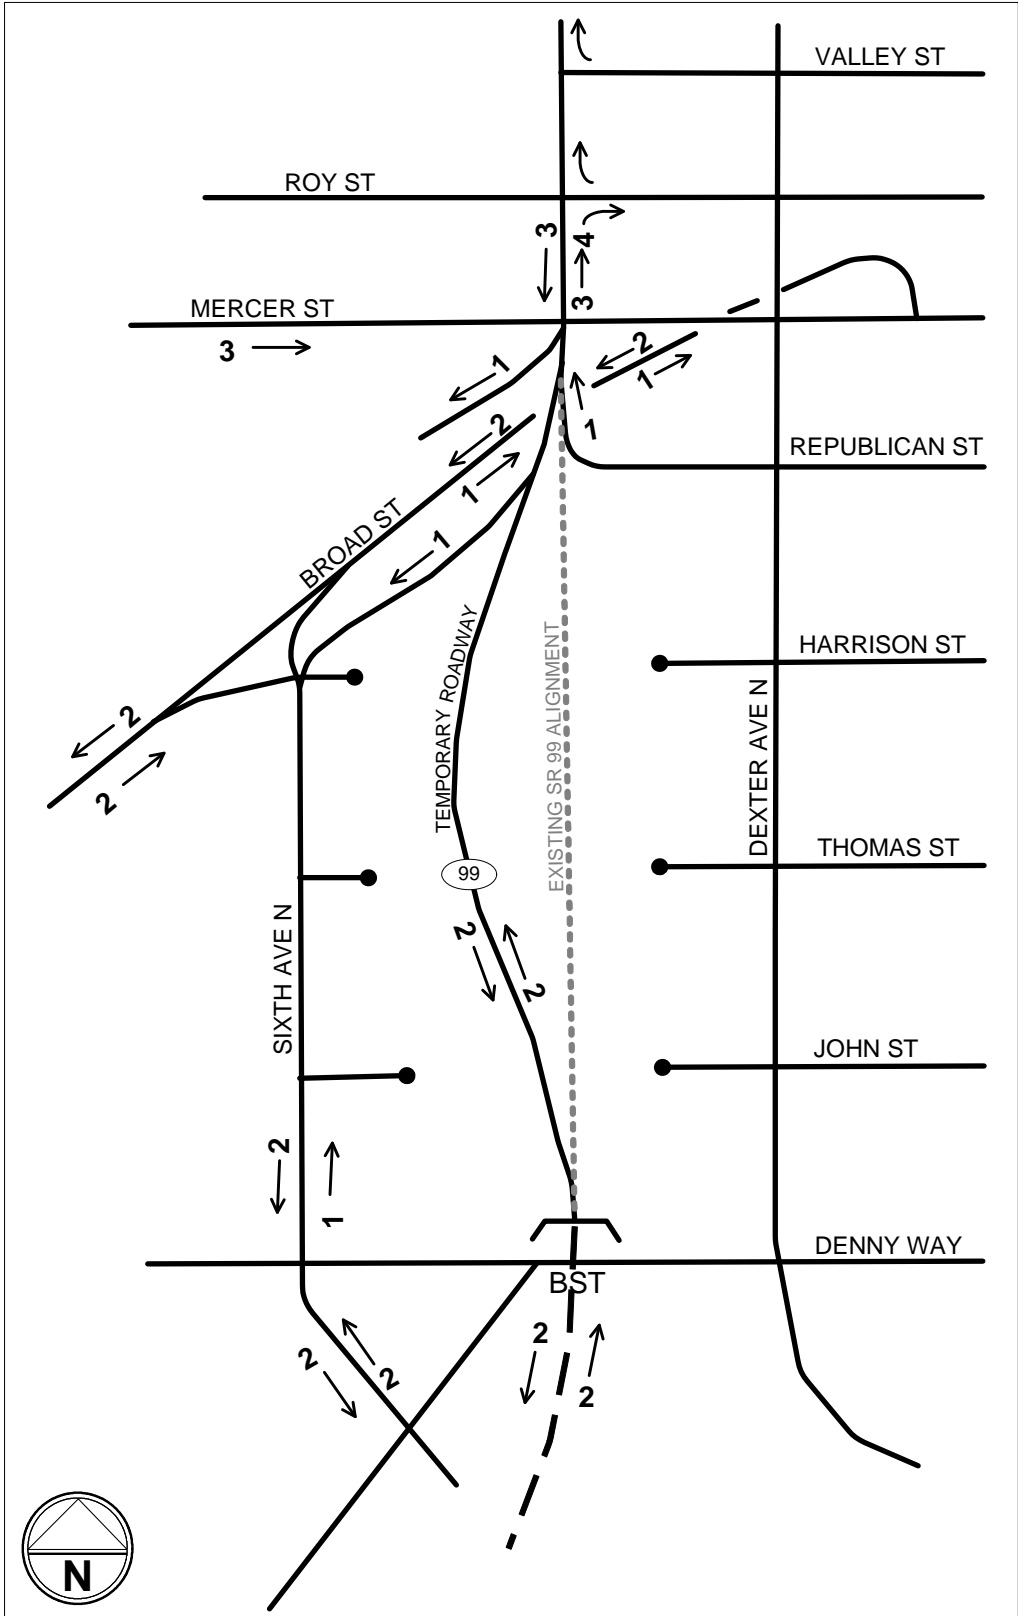

Exhibit 6-10
Roadway Configuration during
Traffic Stage 7 - North End

1 For the AM peak hour in the northbound direction, the slow speeds (about
2 16 mph) predicted for the segment between the Seneca Street and Western
3 Avenue off-ramps are pushed upstream due to the reduced capacity segment of
4 SR 99 in the stadium area that would occur during Traffic Stage 7. As a result,
5 northbound traffic in the segment between S. Spokane Street and S. King Street is
6 predicted to experience much slower speeds during construction, with estimated
7 speeds reduced from approximately 40 mph to 15 mph for this segment.
8 However, north of the bottleneck speeds increase to approximately 30 to 35 mph
9 for the remainder of the project area.

10 In the southbound direction during the AM peak hour, speeds during
11 construction are generally similar to Baseline conditions, with some variation
12 between segments based on the location of ramps.

13 Travel Times

14 The travel time indicator was used as a measure of the impact of project
15 construction activities for two typical trip lengths: Woodland Park to S. Spokane
16 Street and Ballard to S. Spokane Street via the Alaskan Way Viaduct. In the AM
17 peak southbound direction, both of these segments are expected to have
18 essentially the same travel time as under Baseline conditions. In the AM peak
19 northbound direction, both segments are projected to experience an increased
20 travel time of about 2 minutes over a total trip time of about 15 minutes. In the
21 PM peak southbound direction, both of these segments are projected to
22 experience about 1.5 minutes of increased travel time. In the PM peak
23 northbound direction, the increase in travel time for both segments is expected to
24 be 0.5 minute or less.

25 6.1.4 Traffic Congestion on Surface Streets

26 This section provides a qualitative discussion of anticipated congestion levels at
27 intersections or intersection groupings for the construction period primarily
28 defined by Traffic Stage 7 of the overall Bored Tunnel Alternative construction
29 program. Vehicle delays at intersections within the three project sub-areas during
30 this 33-month (estimated) construction period would be expected to increase
31 somewhat compared to Baseline conditions. Such delay increases would be
32 heavily influenced by temporary changes to the SR 99 configuration in the north
33 and south, which are expected to reduce mainline capacity, modify access at
34 critical points along the corridor, and potentially lead to the redistribution of
35 north-south mainline traffic demands to local arterials and other parallel regional
36 facilities such as I-5. While specific technical data are not provided in this section,
37 conclusions drawn from preliminary analysis results are given to highlight areas
38 where potential congestion issues may occur.

1 **South Portal Area**

2 Intersection traffic operations in the south portal area during critical stages of
3 construction are likely to show similar or slightly greater levels of congestion than
4 the Baseline scenario. Intersections affected by shifts in traffic demand away from
5 mainline SR 99 to local arterials may experience slightly higher delays. As
6 described in the construction staging summary, northbound and southbound
7 SR 99 under Traffic Stage 7 would be reduced to two lanes between
8 approximately Columbia Street and the stadium area. With this capacity
9 reduction in effect, some trips originating from or destined to the downtown core
10 may use the ramps to/from the south in the stadium area as a substitute for more
11 direct access at the Seneca Street (northbound) off-ramp and Columbia Street
12 (southbound) on-ramp.

13 Redistribution of traffic to local arterials would potentially cause additional
14 congestion on major north-south routes such as Second and Fourth Avenues.
15 Preliminary delay results reflecting the construction scenario (e.g., Traffic Stage 7)
16 indicate that delays at the majority of intersections investigated would not change
17 substantially compared to Baseline conditions. However, those intersections that
18 do show potential increases in delay for the construction period are generally
19 located along Second and Fourth Avenues and north of Main Street.

20 **Central Area**

21 During the construction scenario, again primarily reflecting Traffic Stage 7, traffic
22 congestion at intersections in the central sub-area would be similar to Baseline
23 conditions. While peak hour volumes are generally expected to increase for the
24 majority of intersections along north-south arterials such as First, Second, and
25 Fourth Avenues, the magnitude of these increases would not result in high levels
26 of congestion for most of these locations. In fact, preliminary analysis results
27 show that only key intersections at or near the SR 99 ramps to/from Seneca and
28 Columbia Streets would experience elevated levels of congestion (LOS E or
29 worse) compared to intersections outside of these areas. These findings are
30 consistent with Baseline conditions, which also show fairly high delays at the on-
31 and off-ramp intersections during the AM or PM peak hours.

32 **North Portal Area**

33 Preliminary analysis findings show that potential congestion impacts due to
34 construction activity in the north end would be greater than those anticipated for
35 the central and south sub-areas. The primary changes to the traffic network in the
36 north end, outside of widening and conversion of Mercer Street to a two-way
37 corridor, are the temporary removal of the Denny Way on- and off-ramps and
38 restrictions on access to/from SR 99 south of Mercer Street. These access
39 modifications would shift a large proportion of downtown-based peak hour

1 traffic to upstream or downstream connections to/from the street grid. In the
2 southbound direction, a temporary connection from SR 99 near Republican Street
3 over to Sixth Avenue would be provided to accommodate trips into downtown
4 and to Seattle Center and the Queen Anne and South Lake Union neighborhoods.
5 Southbound traffic on SR 99 would also be expected to use the existing Battery
6 Street off-ramp (just south of the Battery Street Tunnel) to a greater degree.

7 In the northbound direction, traffic would not be able to exit SR 99 until Roy
8 Street. Previous access to SR 99 from the heavily used Denny Way northbound
9 on-ramp (particularly during the PM peak hour) would likely shift to access
10 points along Dexter Avenue at Republican Street and north of Mercer Street, and
11 upstream to the Western Avenue on-ramp.

12 Peak hour congestion levels at intersections near these affected on- or off-ramp
13 connections or along affected arterials would potentially increase due to higher
14 concentrations of peak hour traffic demand. Preliminary analysis data indicate
15 that many of the affected locations near these ramp areas would operate at LOS E
16 or worse due to substantial redistribution of Denny Way ramp traffic to alternate
17 access to/from SR 99. In addition, east-west traffic impacts due to Mercer Street
18 reconstruction would cause further increases in traffic volumes at critical
19 convergence locations such as Mercer Street at Dexter Avenue and Mercer Street
20 at Westlake Avenue.

21 **6.1.5 Roadway Connectivity and Access**

22 As outlined previously, eight traffic stages have been identified for the Bored
23 Tunnel Alternative, with each stage varying in roadway connectivity and access.

24 During Traffic Stage 1, which would last approximately 5 months, mainline SR 99
25 would be open from S. Holgate Street to Denny Way. Ramp connections would
26 be maintained, except for the Railroad Way ramps; these ramps would be
27 removed and access would be unavailable until Traffic Stage 2. Roadway
28 connectivity and access north of Denny Way would be unaltered.

29 During Traffic Stage 2, which would last approximately 3 months, the SR 99
30 Railroad Way northbound on-ramp and southbound off-ramp in the stadium area
31 would be moved to newly constructed transitional ramp structures. The Denny
32 Way ramps would remain open, as would other ramps north of the stadium area.
33 Roadway connectivity and access north of Denny Way would be unaltered.

34 During Traffic Stage 3, which would last approximately 5 months, the SR 99
35 northbound traffic would travel on the existing viaduct, with southbound traffic
36 using the new transition structure that would replace the Railroad Way ramps
37 near First Avenue S. The northbound on-ramp and southbound off-ramp would
38 be on the new transitional ramp structures. As in Traffic Stage 2, ramps north of

1 the stadium area would remain open. Roadway connectivity and access north of
2 Denny Way would be unaltered.

3 During Traffic Stage 4, which would last approximately 4 months, both
4 northbound and southbound SR 99 would be on the temporary transition
5 structure, with the northbound and southbound ramps open. Ramps north of the
6 stadium area would remain open for use.

7 During Traffic Stage 5, which would last approximately 7 months, SR 99
8 northbound and southbound traffic would travel on the southbound lanes of the
9 west mainline structure. The northbound and southbound ramps would be
10 operational on the newly built transition structure.

11 Traffic Stage 6 represents the month that the SR 99 mainline would be closed in
12 both directions. A temporary roadway along First Avenue S. would be open for
13 north-south traffic. In the north, the Denny Way ramps would be closed.

14 During Traffic Stage 7, which would last approximately 33 months, the SR 99
15 northbound and southbound traffic would travel on the southbound mainline
16 structure, and the northbound and southbound ramps would be open on the
17 transition structure.

18 During Traffic Stage 8, which would last approximately 12 months, the SR 99
19 mainline would be open and using the newly constructed bored tunnel. In the
20 north end, the Harrison Street/Aurora Avenue ramps would be operational.

21 Local Street Access

22 Construction activities would result in disruptions to several streets within the
23 project area, most notably S. Royal Brougham Way, S. Atlantic Street, Alaskan
24 Way S., E. Marginal Way S, First Avenue S., Denny Way, Sixth Avenue N., and
25 John, Thomas, and Harrison Streets.

26 Given the closure of S. Royal Brougham Way between the existing Alaskan
27 Way S. alignment and First Avenue S. by the S. Holgate Street to S. King Street
28 Viaduct Replacement Project, maintaining access on S. Atlantic Street is of critical
29 importance. This roadway would remain open throughout the construction
30 period. A minimum of four lanes would be provided east of Colorado Avenue S.,
31 with two or more lanes connecting to E. Marginal Way S.

32 Construction activities would relocate Alaskan Way S. east of its current
33 alignment and would modify connections between S. Atlantic Street and
34 E. Marginal Way S. Temporary connections would be provided as necessary to
35 maintain these routes throughout the construction period.

36 The relocated southbound off-ramp from SR 99 would direct traffic to
37 southbound Alaskan Way S. and S. Atlantic Street. A minimum of two

1 southbound/eastbound lanes would be maintained on these streets to
2 accommodate these trips.

3 First Avenue S. would be reduced to one lane in each direction between Railroad
4 Way S. and S. Royal Brougham Way in Traffic Stage 1 and between S. King Street
5 and S. Royal Brougham Way in Traffic Stages 2, 3, and 4. First Avenue would
6 then operate on a temporary decking roadway surface from Traffic Stages 4
7 through 7. During Traffic Stage 8, this segment of First Avenue S. would
8 experience temporary lane closures for street restoration. Denny Way, Sixth
9 Avenue N., and John, Thomas, and Harrison Streets would be subject to lane
10 closures and/or restricted use in Traffic Stages 2, 3, 4, and 8 to support utility
11 work.

12 Local access to businesses within the project area would be maintained
13 throughout the construction period.

14 **6.1.6 Transit Services**

15 During construction, two lanes in each direction would be maintained on SR 99.
16 Also, connections to/from SR 99 would be maintained in areas where current access
17 exists; locations include the Seneca Street off-ramp and Columbia Street on-ramp in
18 downtown Seattle. King County Metro bus services using SR 99 would be affected
19 by lane reductions during the construction period. During construction, congestion
20 is expected to increase and result in marginally slower travel speeds on SR 99.
21 Therefore, buses using SR 99 (primarily those that travel between West Seattle/South
22 King County and downtown) would experience slightly longer travel times.
23 Although transit access routes would be maintained, King County Metro may decide
24 to make some routing changes to help lessen the expected congestion effects.

25 Traffic that is projected to divert from SR 99 and use either First Avenue S. or Fourth
26 Avenue S. would affect overall traffic operations. If no specific transit priority
27 strategies are implemented as part of the construction mitigation program, transit
28 operations on First and Fourth Avenues S. would likely experience degraded
29 operations. Additionally, during corridor closures on nights and weekends during
30 construction, buses would need to use alternate routes. Options include SR 99, First
31 Avenue S., and Fourth Avenue S., each with various possible transit priority
32 treatments along the alignment.

33 General traffic travel time variations due to construction that involve major bus
34 corridors are identified in Exhibit 6-11. The corridors assessed are Ballard/
35 downtown Seattle along Elliott Avenue and West Seattle/downtown Seattle and
36 South King County (Burien/downtown Seattle) using SR 99.

1 **Exhibit 6-11. 2015 Construction-Related Travel Times (in minutes) Along Major**
 2 **Transit Travel Corridors**

	Baseline	Construction	Change	Baseline	Construction	Change
	AM Peak Hour			PM Peak Hour		
Elliott Avenue (Battery Street Off-Ramp to W. Mercer Place)						
Inbound	5	5	0	5	5	0
Outbound	5	5	0	10	10	0
SR 99 – South End (S. Spokane Street-Seneca/Columbia Street Ramps)						
Inbound	6	10	+4	5	6	1
Outbound	3	4	+1	5	4	-1

3
 4 For Elliott Avenue, travel times would be similar for Baseline and Project
 5 construction conditions. This would be the case for inbound and outbound travel
 6 in both the AM and PM peak hours. For travel along SR 99 between S. Spokane
 7 Street and the ramps at Seneca and Columbia Streets, the durations would be
 8 generally similar. The one exception would be for inbound trips in the AM peak
 9 hour. With construction, the travel time would be about 4 minutes longer than
 10 under Baseline conditions. However, this does not account for the proposed
 11 inbound transit lane leading up to the point where the northbound mainline
 12 transitions from three to two lanes (approximately S. Holgate Street). This lane
 13 would allow transit vehicles to bypass much of the potential peak period
 14 congestion and would mitigate to some degree the added delay caused by
 15 construction.

16 **6.1.7 Truck Traffic and Freight**

17 All traffic, including freight, would be hampered during Traffic Stages 6 and 7 of
 18 the Bored Tunnel Alternative, which are deemed to be the most disruptive stages
 19 in terms of traffic impacts. During Traffic Stage 6, which lasts for 1 month, both
 20 directions of SR 99 would be closed to traffic. Substantial traffic disruptions are
 21 anticipated in the downtown area for many hours of the day during this 1-month
 22 closure. Traffic Stage 7, however, is generally considered the most disruptive
 23 stage to traffic because it is expected to last for 33 months. Alaskan Way would
 24 operate on a detour route between S. King Street and S. Royal Brougham Way in
 25 the south. In the north the southbound Denny Way ramp would be detoured to
 26 Sixth Avenue near Republican Street, and the northbound Denny Way on-ramp
 27 would be detoured via Dexter Avenue and a new connection to SR 99 near
 28 Republican Street.

1 **South**

2 Freight traffic needs to access important freight facilities in the south portion of
3 the study area, including Port of Seattle terminals along the waterfront and the
4 Duwamish industrial area, and to access I-5 and I-90 for longer inter- and intra-
5 region trips. Starting around April 2011, lane closures on First Avenue S. would
6 be necessary. However, the project would maintain at least one lane northbound
7 and one lane southbound along First Avenue S. during construction.

8 During Traffic Stage 6, both northbound and southbound SR 99 would be closed
9 and traffic would need to be diverted to downtown arterials. Because of the
10 anticipated congestion brought about by this temporary closure of SR 99, many
11 longer-distance freight trips may be diverted to I-5 or shift to off-peak periods.
12 During Traffic Stages 6 and 7, a detour would be provided on Alaskan Way
13 between S. King Street and S. Royal Brougham Way to provide access to surface
14 streets for freight traffic. A temporary roadway along First Avenue S. would be
15 available for north-south traffic between S. King Street and the WOSCA site to
16 provide some accessibility through the south portal area.

17 Traffic delays may also be incurred on those routes designated for hauling
18 construction materials and spoils to and from the construction sites. In the south
19 area, the primary construction material haul route would likely be SR 519 (Edgar
20 Martinez Way) to First Avenue S. to the jobsite. First Avenue S. to the jobsite, or
21 SR 99 to the Seneca Street off-ramp to First Avenue to the jobsite from the south
22 may also be used as a haul route, though likely to a lesser extent. Over-legal
23 loads to the south end of the project would likely travel via SR 599 to First
24 Avenue S. to the jobsite. Over-legal loads traveling within the city are required to
25 obtain a special permit, and appropriate routes are selected via the permit
26 approval process.

27 **Central**

28 Freight access to and from the Seattle Ferry Terminal at Colman Dock would be
29 maintained during all construction stages. During Traffic Stage 7, two lanes of
30 traffic in each direction would be maintained on the Alaskan Way Viaduct
31 (southbound structure). Due to constrained capacity under this configuration,
32 speeds for all traffic, including eligible freight vehicles, are expected to be slower
33 than under Baseline conditions. Access to the southbound viaduct structure
34 would be provided via the temporary transitional ramp structures near S. Royal
35 Brougham Way constructed during Traffic Stage 2. Access for freight would still
36 be provided on Alaskan Way along the central waterfront.

1 **North**

2 During Traffic Stage 7, SR 99 would be limited to two lanes in each direction and
3 speed would be reduced to 40 mph between Mercer Street and the north portal to
4 accommodate realignment of SR 99. Freight traffic would no longer be able to use
5 the Denny Way southbound off-ramp and northbound on-ramp. Access for
6 freight to and from this area would be provided by the new connection from the
7 realigned SR 99 to Sixth Avenue N. that would be located somewhere between
8 Republican Street and Thomas Street. Northbound access to SR 99 would be
9 provided by an on-ramp in the vicinity of Republican Street. Mobility and access
10 for freight would be hampered by major construction activities in this area during
11 Traffic Stage 7. It is likely that many freight vehicles would consider using
12 alternate routes, such as I-5, to bypass congestion and delay caused by major
13 construction activities in this area.

14 Preliminary routes designated for hauling construction materials and spoils have
15 been identified, including I-5 to Denny Way to Dexter Avenue N. to the jobsite
16 and I-5 to Mercer Street to the jobsite. SR 99 to and from the north is also
17 available as a potential haul route.

18 Over-legal loads would likely be allowed to travel on state highways during off-
19 peak hours during the day, from 9:00 p.m. to 5:00 a.m. Monday through Friday,
20 and during all hours on the weekends. As noted previously, over-legal loads
21 traveling within the city are required to obtain a special permit, and appropriate
22 routes are selected via the permit approval process.

23 Freight travel in the corridor may be hampered during project construction as
24 construction activities may occur up to 24 hours per day, 7 days per week for the
25 entire construction period within permitting requirements.

26 **6.1.8 Parking**

27 Removal of parking spaces during construction generally includes the spaces that
28 would be permanently affected (as described in Chapter 5), plus those spaces that
29 are needed for construction, staging, or demolition activities. Assuming viaduct
30 demolition occurs in stages, several blocks of parking under the viaduct would be
31 affected at a time while parking would still be available on other blocks. In the
32 whole project area, the total number of on-street spaces that would be affected at
33 one time during construction and demolition would be about 640 to 710 on-street
34 spaces and about 220 to 360 off-street spaces, for a total of up to about 1,070
35 spaces. After viaduct demolition, it is likely that many of the spaces under the
36 viaduct would be affected by the Alaskan Way Surface Street Improvements
37 Project and would not necessarily be returned to use. This project is separate

1 from the Alaskan Way Viaduct Replacement Project and is discussed in more
2 detail in Section 7.3.4, Parking, in the Cumulative Effects chapter.

3 The locations of parking removals are shown in Exhibits 6-12 and 6-13. Exhibit 6-14
4 summarizes the parking effects during construction. In addition to the spaces shown
5 in the table, there may be short-term (such as peak period) parking restrictions on
6 some streets near the portals to help accommodate transit or general purpose traffic
7 during construction.

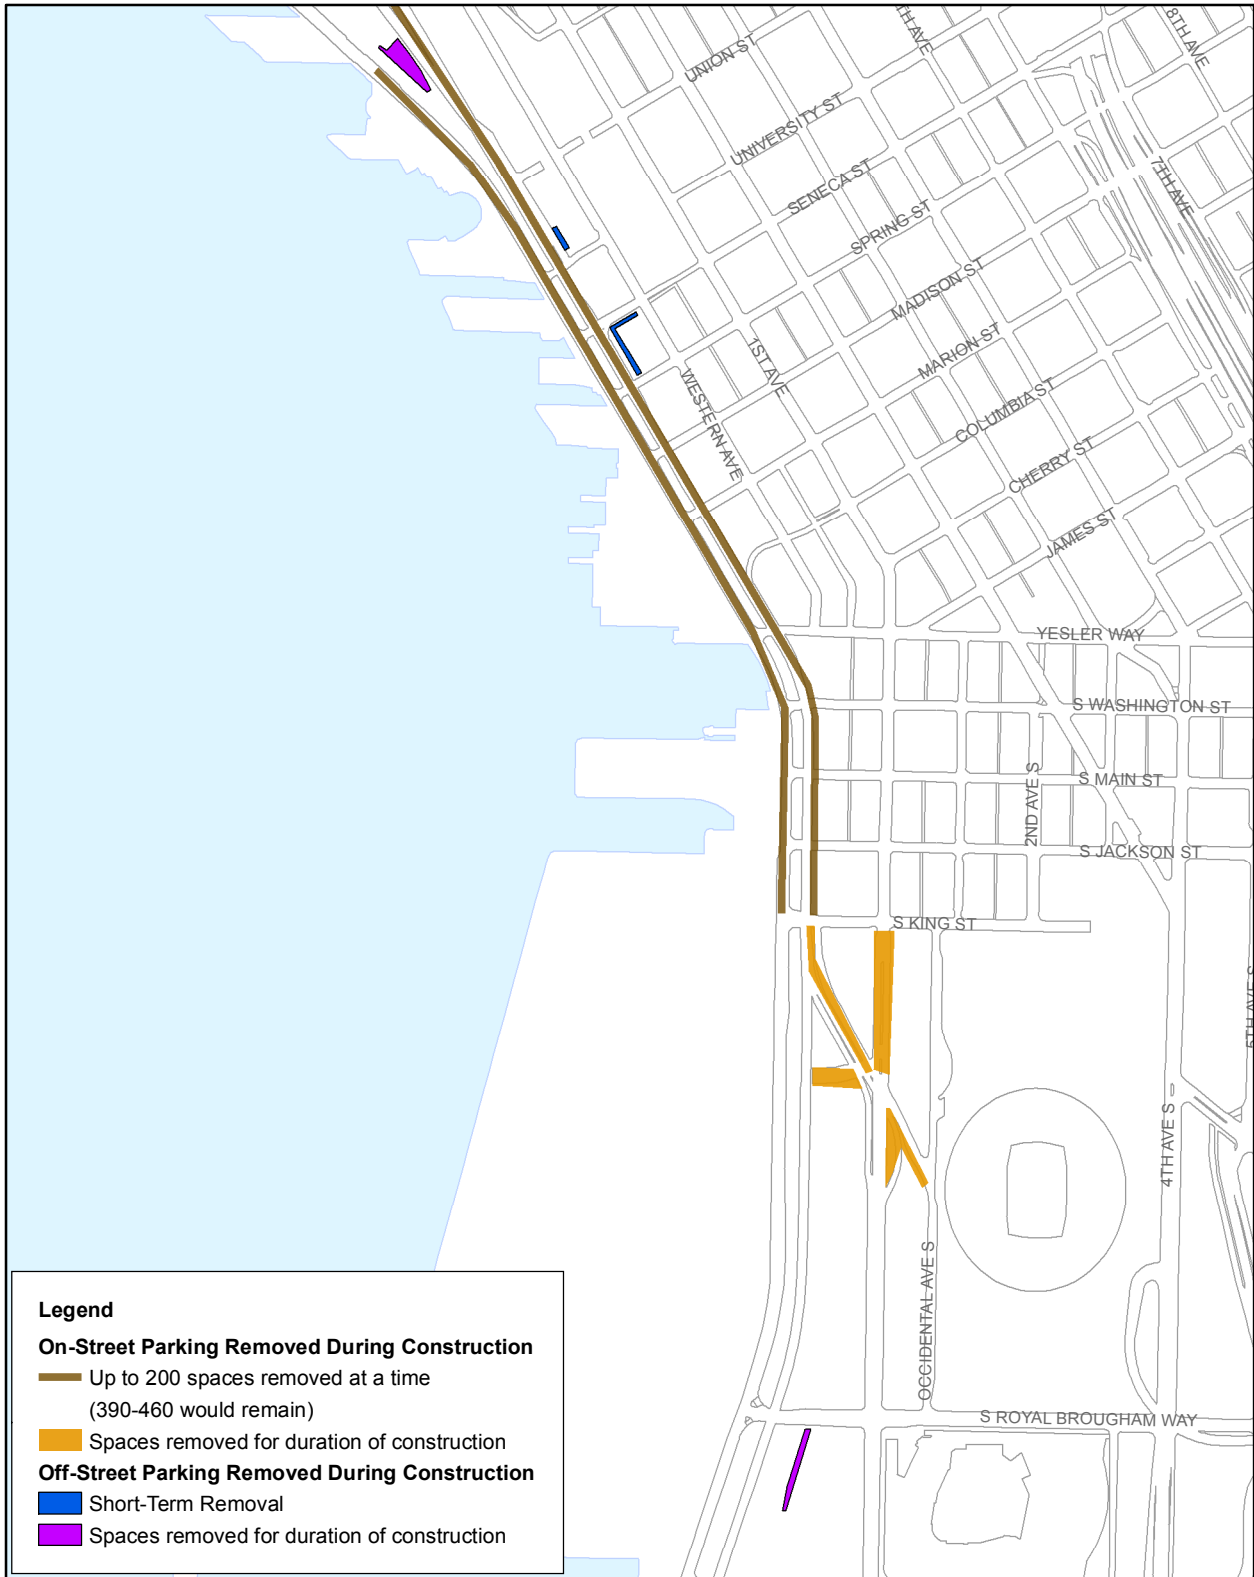

8 **South Portal Area**

9 In the south portal area, south of S. King Street, about 210 on-street and 50 off-
10 street spaces would be removed during construction. Of the on-street spaces,
11 most are short-term parking, although about 40 long-term spaces would be
12 removed as well. The majority of the on-street parking space removals would be
13 along Railroad Way and under the ramps. The 50 off-street spaces that would be
14 affected are located in a public pay lot south of S. Royal Brougham Way, behind
15 Pyramid Alehouse.

16 The removal of about 260 parking spaces in the south portal area is not anticipated to
17 cause a large impact, although some drivers may be slightly inconvenienced. The on-
18 street parking removals along First Avenue S. between S. King Street and Railroad
19 Way may affect customer parking for adjacent businesses. However, on-street parking
20 would continue to be available a block to the north and along S. King Street.

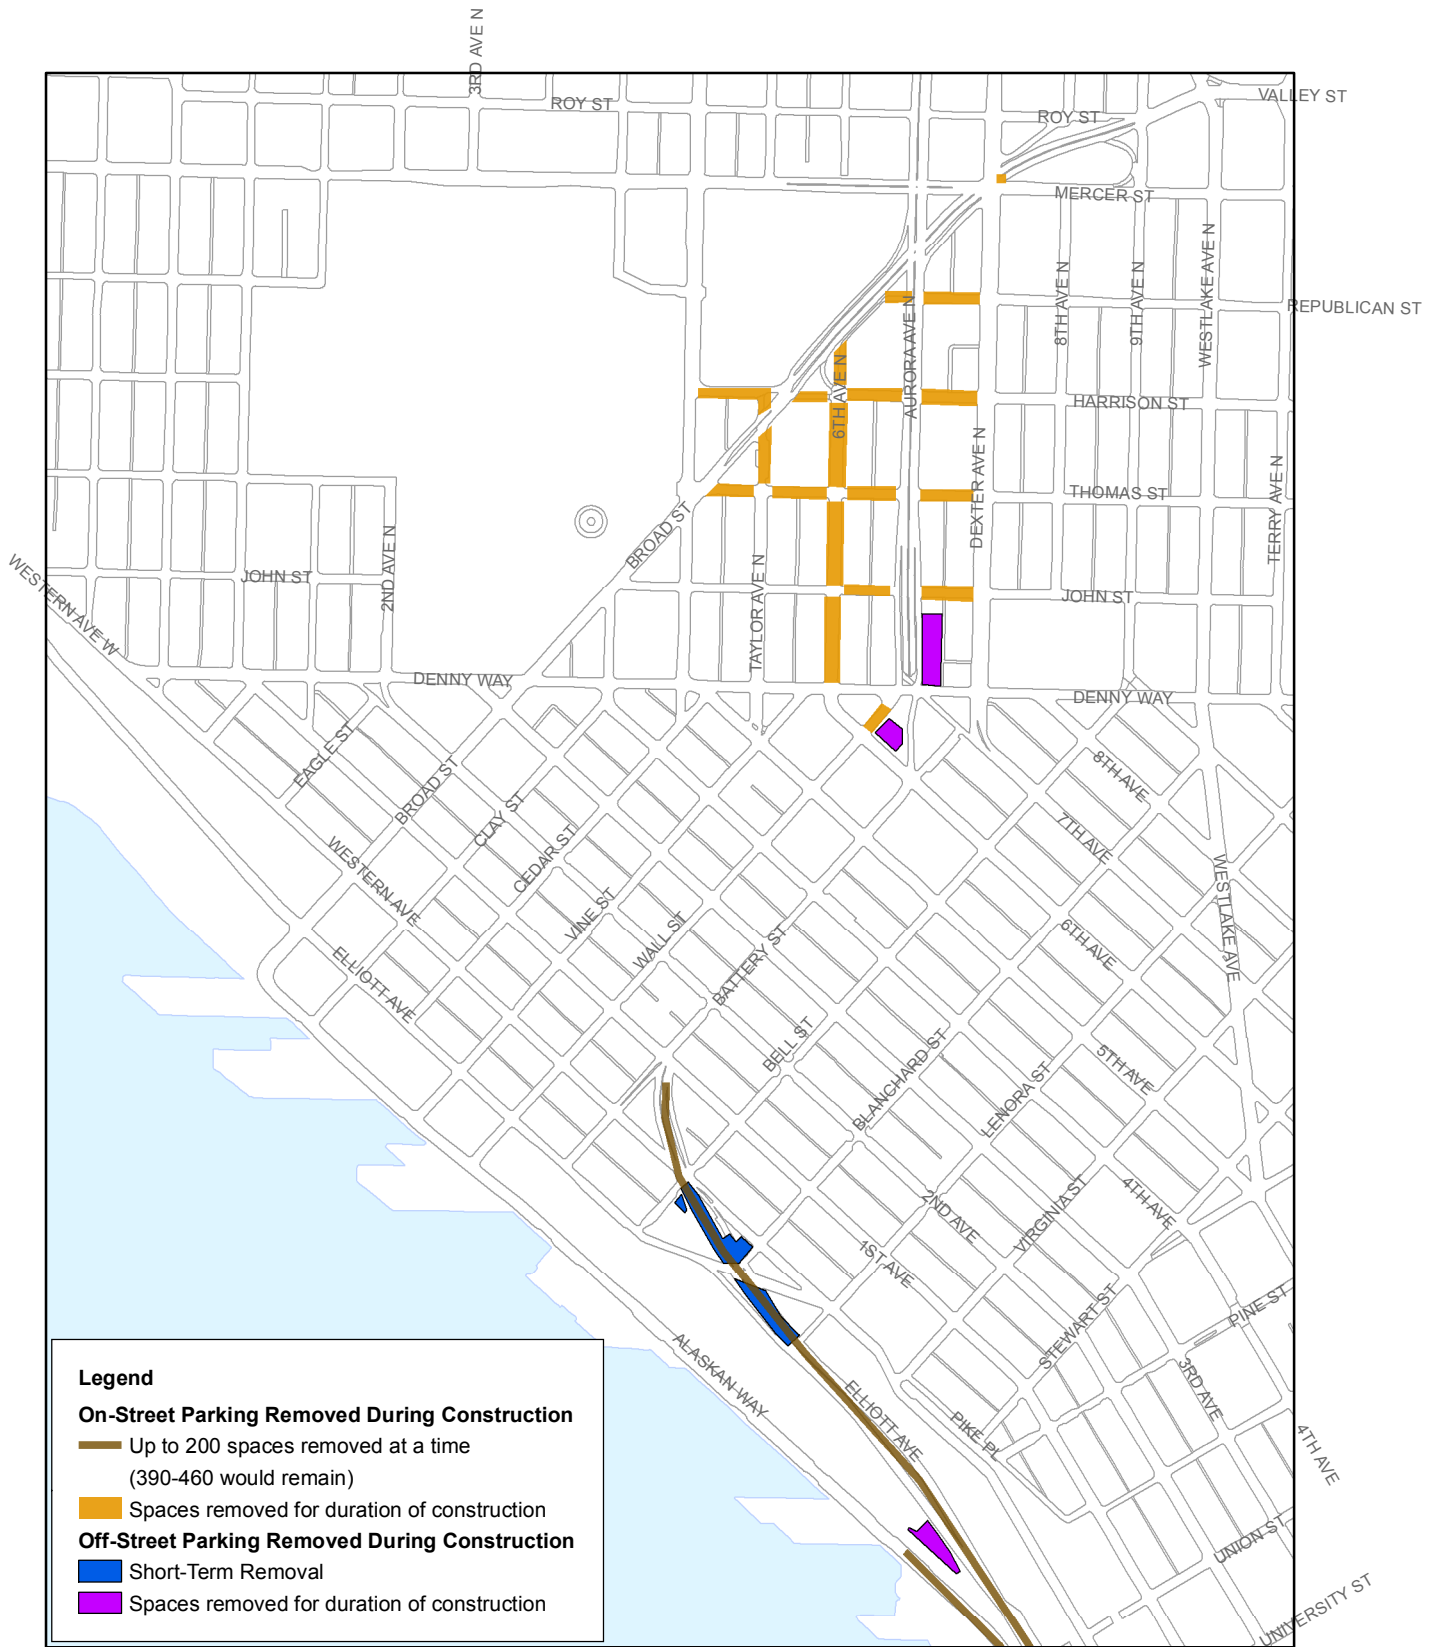

21 Although parking would be reduced compared to today's conditions, ample
22 parking is expected to be available in pay lots near the stadiums. Pay lots in the
23 stadium area are abundant and underutilized on non-event days. The off-street
24 parking utilization rate for the stadium area is about 31.1 percent on an average
25 non-event weekday (PSRC 2006), suggesting that it is relatively easy to find a pay
26 parking space in the stadium area. In addition, most surface streets in the SODO
27 area allow on-street parking, and some of it is long-term, particularly farther
28 south.

29 During events such as Seahawks, Mariners, and Sounders games, parking is
30 currently highly utilized, and private lots charge a premium for event parking.
31 Only about 50 off-street parking spaces would be removed during project
32 construction, which is not expected to noticeably affect the overall parking supply
33 in the stadium area. Approximately 6,900 off-street parking spaces are available
34 in the major parking facilities near the stadiums.

Exhibit 6-13
Locations of Parking Affected
During Construction - North

1 **Exhibit 6-14. Construction Parking Effects of the Bored Tunnel Alternative**

	On-Street Spaces			Off-Street Spaces	Total Spaces
	Short-Term	Long-Term	Subtotal		
South Portal Area	170	40	210	50	260
Central - spaces affected at the same time	130 to 200	0 to 10	130 to 200*	70 to 210	Up to 410
North Portal Area	70	230	300	100	400
Total	Up to 440	Up to 280	Up to 710*	Up to 360	Up to 1,070

2 * The maximum number of short- and long-term spaces would not be affected at the same time.

3 **Central**

4 There are approximately 590 on-street parking spaces under the viaduct from
 5 S. King Street to the Battery Street Tunnel portal and along Alaskan Way between
 6 S. King Street and Pine Street. All of these spaces would be affected at some point
 7 during viaduct demolition, but they would not all be removed at the same time.
 8 It is anticipated that two demolition crews would each work on two blocks at a
 9 time, so four blocks of parking would be affected for approximately 1 month at a
 10 time during demolition. This would affect about 130 to 200 on-street spaces at a
 11 time along Alaskan Way and under the viaduct during demolition activities. The
 12 majority of the on-street parking spaces would remain in use. Exhibit 6-15 lists
 13 the affected and available on-street parking spaces along the waterfront.

14 **Exhibit 6-15. Effects to On-Street Parking Spaces During Viaduct Demolition –**
 15 **Central**

	Spaces Affected at the Same Time	Spaces Remaining at Any Given Time
Under the viaduct and ramps (S. King Street to Battery Street Tunnel)	120-170	370-420
Alaskan Way surface street (S. King Street to Pine Street)	0-20	20-50
Total	130-200	390-460

16
 17 Although on-street spaces along the Alaskan Way surface street are not under the
 18 viaduct, they would be affected because demolition activities would likely
 19 encroach on Alaskan Way. To maintain traffic lanes, parking would need to be
 20 restricted along several blocks of Alaskan Way. Much of the on-street parking
 21 along Alaskan Way consists of loading and taxi waiting areas. These types of
 22 spaces would likely be able to be accommodated within a block or two of their
 23 existing locations and would only be relocated for a month or two at a time.

1 About 70 off-street spaces in the central area (S. King Street to the Battery Street
 2 Tunnel) would be affected for the duration of construction. Refer to Exhibit 6-16
 3 for a table of affected off-street parking spaces. Parking removals during
 4 construction would affect about 70 spaces in a public parking lot between
 5 Alaskan Way and the viaduct, north of the Seattle Aquarium. Portions of two lots
 6 just east of the viaduct, one at Seneca Street and one at University Street, would
 7 result in a loss of about 40 spaces for about a month, if they are affected at the
 8 same time. The number of affected off-street spaces does not include the parking
 9 lot on Pier 48 at about S. Main Street, adjacent to Pioneer Square, which may be
 10 used for contractor staging or construction worker parking. Although this lot is
 11 currently used for some public parking, the public parking is a temporary
 12 condition, and public pay parking is not an allowable permanent use on that pier.
 13 Near Elliott and Western Avenues, up to about 140 off-street spaces in the lots
 14 under the viaduct between Lenora Street and Bell Street would be removed
 15 during demolition of this section of the viaduct. This section of the viaduct is
 16 considered to be one of the more complicated sections to remove, so removal
 17 could take several months.

18 **Exhibit 6-16. Off-Street Parking Spaces Affected During Construction/Demolition –**
 19 **Central**

	Affected Throughout Construction	Affected for Several Months
Pioneer Square area (S. King Street to Columbia Street)	-	-
Central Waterfront (Columbia Street to Pine Street)	70	40 ¹
Elliott/Western vicinity	-	140 ²
Total	70	Up to 140 at one time ³

20
21
22
23
24

Notes:

1. This represents parts of two different lots that could be affected at the same time during demolition.
2. Of the 140 spaces, 75 of these are only available to the public during evening/weekend hours.
3. The total is 140, not 180, because all of the lots would not be affected at the same time.

25 In addition to the public parking that would be affected during viaduct
 26 demolition, about 140 private and reserved spaces are located under or adjacent
 27 to the viaduct that are not listed in the tables above. Individual block faces have
 28 between 0 and 30 private or reserved spaces along the west side of the buildings/
 29 loading docks, with an average of about 15 of these spaces per block. Each block
 30 would experience parking removals for approximately 1 month due to viaduct
 31 demolition activities. Up to four blocks could be affected at a time, or up to about
 32 90 spaces. The private and reserved spaces are primarily used by adjacent
 33 businesses for customer and employee parking, and for loading in some cases.

1 Many of the piers along the central waterfront have loading spaces and employee
2 and customer parking on the piers, with access from Alaskan Way. Although
3 there would be on-street parking removals along Alaskan Way, access to the piers
4 is not anticipated to be restricted during viaduct demolition, so the parking and
5 loading on the piers would remain available.

6 With up to about 600 parking spaces affected during viaduct demolition, it may
7 become more difficult to find parking along the central waterfront and in Pioneer
8 Square during demolition. This could result in drivers looking for parking spaces
9 several blocks farther from their destinations than they would normally seek
10 parking, or entering pay lots instead of finding on-street parking.

11 There are numerous off-street parking lots near the central waterfront. Based upon
12 PSRC data from 2006 on off-street parking lots and garages, over 2,700 off-street
13 parking spaces are available within about one block of the viaduct between S. King
14 Street and the Battery Street Tunnel south portal. The large parking garage across
15 from Bell Harbor Conference Center on Western Avenue between Wall and Bell
16 Streets (the Pier 66/Art Institute garage) provides an additional 1,700 spaces.

17 The City of Seattle commissioned a parking count on a Saturday in August 2006
18 to capture the parking demands for a busy summer weekend near the central
19 waterfront (Nelson \ Nygaard Consulting Associates 2008). The study found that
20 surface lots were fullest, reaching close to 100 percent capacity by 2:00 pm. The
21 Pike Place Market garage also reached close to 100 percent capacity by 2:00 pm.
22 Other garages farther from Pike Place Market, such as the Pier 66/Art Institute
23 garage, were less full, filled to between 52 and 64 percent of capacity throughout
24 the day.

25 North Portal Area

26 In the north portal area, about 300 on-street and 100 off-street spaces would be
27 removed during construction. Of the affected on-street parking spaces, the
28 majority are long-term spaces, as identified previously in Exhibit 6-12. The on-
29 street parking removals include spaces on the following streets:

- 30 • Sixth Avenue N. from Denny Way to Broad Street
- 31 • John Street from Sixth Avenue N. to Dexter Avenue N.
- 32 • Thomas Street from Broad Street to Dexter Avenue N.
- 33 • Harrison Street from Fifth Avenue N. to Dexter Avenue N.
- 34 • Republican Street from Broad Street to Dexter Avenue N.
- 35 • Dexter Avenue N. between Mercer and Broad Streets

36 In the north portal area, about 100 off-street spaces in two public parking lots
37 would be affected during construction. One lot has about 80 spaces on the

1 northeast corner of Denny Way and Aurora Avenue. The second lot, on the east
2 corner of Sixth Avenue N. and Wall Street, has about 20 spaces.

3 Some private and business parking would be affected by property acquisitions;
4 however, these are not parking lots available to the public. These properties are
5 addressed in the property acquisitions discussion in Appendix G, Land Use
6 Discipline Report.

7 Near the north portal, on-street parking would still be available within several
8 blocks of the spaces that would be removed. Furthermore, there are numerous off-
9 street lots within several blocks of the parking removals. Not including the lots that
10 would be affected by project construction, over 3,100 pay spaces are available
11 between Denny Way and Roy Street, and Fifth Avenue N. and Dexter Avenue,
12 according to 2006 PSRC data. The 3,100 spaces takes into account the removal of
13 spaces for Gates Foundation construction and the new Fifth Avenue Parking Garage.
14 With the removal of 400 parking spaces, there would continue to be nearby parking
15 options; however, it may become slightly more difficult to find parking on event
16 days, and parking in some lots could potentially become more expensive in response
17 to the reduction in the adjacent parking inventory.

18 Construction Worker Parking

19 The project construction workforce would consist of up to about 1,300
20 construction workers. The work areas for these construction workers would be
21 located in several different locations, with concentrations near the south portal,
22 north portal, and central waterfront as demolition is occurring. Construction
23 workers who are not able to park within the construction zone would likely seek
24 available long-term parking in the area, first pursuing on-street spaces, then pay
25 lots.

26 Parking Mitigation

27 The following strategies could help minimize the use of visitor/customer parking
28 by construction workers during project construction.

- 29 • Develop a Construction Worker Parking Plan to identify appropriate
30 parking options for construction workers and discourage use of short-
31 term visitor/customer parking in the project vicinity.
- 32 • Provide strong enforcement of the short-term parking regulations in the
33 immediate project area (two- to three-block radius). The goal is to ensure
34 a constant supply of short-term parking for customers of central
35 waterfront businesses and to prevent use of these spaces by construction
36 workers.

1 In addition to the strategies to address construction worker parking, a number of
2 parking mitigation strategies could be implemented to address parking
3 disruption by construction activities. However, these strategies are not
4 anticipated to be put in effect solely for the Bored Tunnel Alternative, but would
5 address parking effects related to the construction of the overall Program. The
6 Program is expected to have a more substantial effect on parking, and the
7 cumulative effects from all of the Program elements may warrant consideration
8 for parking mitigation. This is discussed in more detail in Section 7.3.4, Parking,
9 in the Cumulative Effects chapter. Potential parking mitigation strategies for the
10 central waterfront area include the following:

- 11 • Provide pedestrian and parking maps in advance of and during
12 construction for businesses (at no cost to the businesses) to mail to clients
13 and vendors.
- 14 • Increase the short-term maximum meter time from 2 hours to at least 3
15 possibly 4 hours since the average trip to the waterfront is estimated at 3
16 to 4 hours.
- 17 • Provide a low rate for the first 4 hours and much higher rates for full-day
18 parking use to encourage short-term visitor/customer parking and
19 discourage long-term employee parking.
- 20 • Encourage privately held lots to institute parking pricing that rewards
21 short-term parking.
- 22 • Build a new parking facility in proximity to the waterfront to provide
23 short-term visitor and customer parking.
- 24 • Coordinate with private and public lots to install real-time automated
25 overhead signs that display where parking is available as drivers enter the
26 central waterfront zone.
- 27 • Encourage businesses to adopt parking vouchers that they could give to
28 customers to park in designated parking lots.

29 6.1.9 Pedestrians

30 Major construction efforts are disruptive to all forms of transportation, and
31 pedestrian travel in and around the construction zone would experience
32 disruption of sidewalk and trail facilities use. Localized sidewalk closures for
33 utility relocation, construction, demolition, and restoration activities would
34 require detours of short duration and distance for pedestrians. However, the
35 duration of disruption and out-of-direction travel would be minimized to the
36 extent practicable to maintain pedestrian mobility and accessibility.

37 Traffic diverting to arterial and local streets during construction could make it
38 more difficult for pedestrians to cross streets. In particular, First Avenue S.,

1 Fourth Avenue S., Denny Way, and Dexter Avenue N. are anticipated to carry
2 increased volumes of traffic during construction.

3 South Portal Area

4 Pedestrian access in the south portal area would be maintained during all phases
5 of construction via the combined pedestrian/bicycle trail on the west edge of the
6 project area that runs adjacent to the Port of Seattle facilities. The combined
7 pedestrian/bicycle facility would extend from S. King Street to S. Atlantic Street
8 and would connect to existing pedestrian facilities requiring minimal to no out-of-
9 direction travel.

10 First Avenue S. from S. Plummer Street to S. Jackson Street would experience
11 intermittent sidewalk closures due to utility relocations during the early
12 construction phases, as well as additional traffic on First Avenue S. due to the
13 closures on Alaskan Way. When a sidewalk closure is required, pedestrians
14 would experience a limited amount of out-of-direction travel to use sidewalk
15 facilities on the opposite side of the roadway or might be required to detour to
16 parallel roadways.

17 East-west travel within the construction zone (S. King Street to S. Royal
18 Brougham Way) would be restricted for a majority of the traffic stages. East-west
19 access by pedestrians would be largely restricted to S. Atlantic Street and
20 S. Jackson Street, due to the presence of construction staging areas and the need
21 for temporary roadway facilities in this area.

22 North Portal Area

23 Pedestrian facilities and access in the northern project area during construction
24 would likely be closed on both the western and eastern sides of SR 99 from
25 approximately Mercer Street to Denny Way due to building demolition, utility
26 relocation, construction, and restoration activities.

27 Pedestrians on the west side of SR 99 would be detoured to Sixth Avenue during
28 the majority of the project's construction period. Pedestrians using sidewalks on
29 the east side of SR 99 would be diverted to Dexter Avenue N. and associated east-
30 west side streets to access businesses in this area. Some east-west pedestrian
31 travel on Mercer and Broad Streets would be affected and experience restrictions
32 during construction activities. East-west pedestrian mobility in this area is
33 already challenging due to limited crossings of SR 99. Particular attention would
34 be given to minimize the duration of closures and out-of-direction travel by
35 maintaining sidewalk facilities on the opposite side of the roadway. Construction
36 on Mercer Street would be substantially complete prior to the closure and filling
37 of Broad Street, which would maintain pedestrian mobility across SR 99 in this
38 area.

1 **6.1.10 Bicycles**

2 Generally, bicyclists would face the same lane reductions and closures as other
3 traffic. Bicyclists riding in the street may face increased potential for conflicts
4 with vehicles, given the expected higher traffic volumes and limited travel lanes
5 and reduced space to maneuver on some streets. In particular, First Avenue S.,
6 Fourth Avenue S., Denny Way, and Dexter Avenue N. are anticipated to carry
7 increased volumes of traffic during construction.

8 **South Portal Area**

9 As was noted for pedestrians, during all phases of construction bicycle access
10 would be maintained on the combined pedestrian/bicycle trail on the west edge of
11 the project area that runs adjacent to the Port of Seattle facilities. The combined
12 pedestrian/bicycle facility would extend from S. King Street to S. Atlantic Street
13 and would connect to existing bicycle facilities on either end, with minimal to no
14 out-of-direction travel.

15 First Avenue S. from S. Plummer Street to S. Jackson Street would be reduced to
16 one lane of traffic during much of the construction period. Bicyclists would have
17 the options of continuing to use First Avenue S., using the combined pedestrian/
18 bike trail on the western edge of the project area, or diverting to Occidental
19 Avenue S. in the immediate project area.

20 Depending on the origin or destination of the cyclist, they may choose to travel on
21 Fourth Avenue S., sharing the roadway with other vehicular traffic. The existing
22 in-street bicycle lanes on Second Avenue and Fourth Avenue through downtown
23 would be maintained throughout the construction period.

24 As noted for pedestrians, east-west bicycle travel between S. King Street and
25 S. Atlantic Street would be restricted during nearly all traffic stages.

26 **North Portal Area**

27 Generally, bicyclists would face the same lane reductions and closures as other
28 traffic in the northern project area. However, much of the construction would
29 take place on SR 99, where bicycle travel is not allowed; therefore, cyclists are
30 expected to experience fewer direct impacts to north-south travel, particularly as
31 the in-street, southbound bicycle lane on Dexter Avenue N. would be maintained
32 during all construction activities. However, increased traffic volumes are
33 expected on Dexter Avenue N. and other parallel facilities, which may increase
34 the potential for auto and bicycle conflicts.

35 East-west bicycle travel on Mercer Street would experience the same lane
36 reductions and temporary closures as those expected for auto traffic. As noted for
37 pedestrian travel, particular attention would be given to minimize the duration of

1 closures and, when possible, to schedule closures during less disruptive times.
2 Construction on Mercer Street, including the combined pedestrian/bicycle facility
3 on the north side of the roadway, would be substantially complete prior to the
4 closure and filling of Broad Street, which would maintain bicycle mobility across
5 SR 99 in this area.

6 6.1.11 Ferries

7 The Seattle Ferry Terminal at Colman Dock at Pier 52 services the most Washington
8 State Ferries customers of any terminal in the system. More recently, this terminal is
9 also being used by passenger-only ferry service provided by King County. The
10 Seattle-Bainbridge route carried over 6 million passengers in 2008, with
11 approximately 3 million of those passengers walking onto the ferry and the
12 remainder driving or riding in a vehicle. The Seattle-Bremerton route carried
13 approximately 2.5 million passengers in 2008, with approximately 1.5 million of
14 those walking onto the ferry (PSRC 2009). Ferry operations, by their nature, result in
15 a very sporadic flow of people and vehicles moving to and from the terminal and
16 put unique demands on the surrounding transportation infrastructure.

17 The primary construction activities that would affect access to and from the Seattle
18 Ferry Terminal are as follows:

- 19 • Alaskan Way would be rerouted to the east between S. Royal Brougham
20 Way and S. King Street in Traffic Stages 1 through 7. This would become
21 the permanent alignment in January 2014.
- 22 • Demolition of the Alaskan Way Viaduct would close sections of Alaskan
23 Way two blocks at a time and would close selected cross streets. Ferry
24 passengers would need to be informed of street closures and short-term
25 detours that may affect their route to and from the Seattle Ferry Terminal.
- 26 • Demolition of the Alaskan Way Viaduct would eliminate the pedestrian
27 overpass that currently connects Colman Dock to First Avenue. Until an
28 alternate structure is constructed, pedestrians would need to cross at the
29 street level.

30 As planning and design of the project and construction staging progresses,
31 coordination with Washington State Ferries staff will continue to take place to
32 ensure that disruptions or degradations to access to and from the Seattle Ferry
33 Terminal are minimized or avoided.

34 6.1.12 Safety

35 Driving in a work zone is more dangerous than on other parts of the road. Drivers
36 can become confused by unfamiliar traffic patterns, signage, and cones/barricades in
37 roadway work zones.

1 FHWA published the Work Zone Safety and Mobility Rule on September 9, 2004,
2 in the Federal Register (69 FR 54562). In accordance with this rule, the project
3 would develop a temporary traffic control plan. This plan would address traffic
4 safety and control throughout the work zone. Work zone management strategies
5 may include using Intelligent Transportation Systems (ITS), traveler information,
6 real-time work zone monitoring, traffic incident management, and enforcement
7 components.

8 6.1.13 Event Traffic

9 South Portal Area

10 Based on existing Safeco Field patronage counts, up to 47,000 attendants can be
11 expected for a full-house baseball event, which may translate to roughly 14,000
12 additional vehicles on local arterials and regional facilities. Seahawks games,
13 though typically held on Sundays, draw even larger crowds and result in greater
14 levels of traffic demand. While a portion of patrons for both types of events
15 travel via ferry or public transit (5,000 to 7,000 persons), with some growth in
16 these modes projected in the future, the majority of these event-goers are likely to
17 continue to travel via private vehicle and/or carpool.

18 Event-related access to/from the stadiums during the construction period would
19 continue to rely on key north-south arterials such as First Avenue S. and Fourth
20 Avenue S., but would also depend on the new two-way S. Atlantic Street facility
21 west of First Avenue S. (The SR 519 Intermodal Access Project – Phase 2 is
22 assumed to be completed.) Event traffic would also continue to use the SR 99
23 ramps to/from the north.

24 As discussed in Section 6.1.4, during construction of the project elements in the
25 south end, access to/from the stadium area would be similar to existing
26 conditions, with the exception of the SR 519 Phase 2 project, which is expected to
27 be completed. For the SR 99 corridor, explicit short-term detours and temporary
28 structures would be used while the project elements in the south portal area are
29 being constructed. These detours would occur for Traffic Stages 2 through 5 and
30 Traffic Stage 7 of the construction schedule and would result in capacity
31 reductions on SR 99. Stadium area ramps to/from the north would be maintained,
32 allowing for similar connections as existing conditions. However, the
33 southbound off-ramp into the area would be temporarily directed to S. Atlantic
34 Street, which eventually converges with heavy traffic on First Avenue S. and
35 regional trip activity on S. Atlantic Street/SR 519 west of First Avenue S.

36 The results of construction activity and changes to ramp connections would
37 include potentially higher levels of congestion in the immediate vicinity of the
38 stadiums and, therefore, longer travel times into and out of parking facilities,

1 particularly during large events. Also, First Avenue S. is expected to be one lane
2 in each direction during most of Traffic Stages 2 through 4, which may exacerbate
3 delays related to the SR 99 capacity reductions and high concentrations of traffic
4 during events. Despite the localized effects of the construction period, mainline
5 traffic congestion would not be affected substantially, based on preliminary
6 construction phase analysis results. The need for temporary detours, lane
7 closures, and general traffic management for all modes prior to and following
8 events would continue throughout the construction period. Particular emphasis
9 on the intersection of S. Atlantic Street and First Avenue S. would be required,
10 because substantial traffic conflicts and demands would occur for all approaches
11 at this location.

12 North Portal Area

13 Based on data collected in 2007 and 2008, over 5,000 events take place annually at
14 Seattle Center, with the largest concentrations of people and traffic occurring
15 during major Key Arena events (high-profile concerts, Seattle Storm playoff
16 games, etc.) and large-scale weekend festivals. Attendance at regional events
17 such as Bumbershoot, Folklife festival, and the Bite of Seattle has been
18 documented to reach up to 60,000 persons daily. Peak loads can be as high as
19 17,000 person trips for a Key Arena event, and as high as 200,000 during a festival
20 weekend such as Folklife or Bumbershoot. Such attendance levels translate fairly
21 directly to high levels of traffic demand in terms of volumes circulating within
22 and around the Seattle Center area.

23 Construction activity in the north end would cause disruptions to these major
24 events at Seattle Center due to temporary lane closures, detours, and access
25 modification to SR 99 ramps. For Traffic Stage 7 (deemed a worst-case snapshot),
26 the reconfigurations of Mercer Street to a two-way arterial from Dexter Avenue to
27 Fifth Avenue would result in temporary lane closures on Mercer Street and a
28 general loss of east-west capacity. Also, construction of the new roadway section
29 for Aurora Avenue between Denny Way and Harrison Street would remove the
30 ramps to/from Denny Way and restrict access to/from SR 99 south of Mercer
31 Street. Such changes would not only affect congestion locally on arterials such as
32 Mercer Street, Fifth Avenue, Dexter Avenue, and Broad Street, but would result
33 in higher levels of congestion on mainline SR 99 due to higher concentrations of
34 on- and off-ramp volumes to designated temporary ramp connections.

35 In fact, preliminary traffic analysis results for weekday peak hour conditions
36 during the construction phase indicate high levels of congestion for a number of
37 intersections in the north end along Dexter Avenue, Westlake Avenue, and
38 Mercer Street. With potentially even higher concentrations of traffic expected
39 during major events at Seattle Center, congestion at local intersections in the

1 Seattle Center area and surrounding neighborhoods such as Queen Anne and
2 South Lake Union may be substantial and could potentially require extensive
3 traffic management tools to minimize vehicle queuing yet still provide efficient
4 and safe travel options for non-motorized modes.

5 A full suite of measures related to signage, signal timing/operations, road
6 closures, and detours would be critical for maintaining reasonable levels of traffic
7 flow/circulation near the Seattle Center area during major events. In addition,
8 Seattle Center's Fiftieth Anniversary celebration will be held from April to
9 October 2012 and may require consideration of additional mitigation measures.
10 Ongoing coordination with Seattle Center would help identify issues and
11 potential mitigation measures.

12 **6.2 Construction Mitigation**

13 WSDOT, King County, and the City of Seattle have developed Transportation
14 Improvements to Minimize Traffic Effects During Construction to keep people
15 and goods moving during construction of the Program. These enhancements and
16 improvements are independent projects that will benefit all pending Program
17 elements. They are designed to increase transit options, shift traffic away from
18 construction areas, and provide drivers with the information they need to choose
19 less congested routes.

20 These plans include the following elements:

- 21 • Variable speed signs and travel time signs on I-5 to help maximize safety
22 and traffic flow.
- 23 • Funding for SR 519 Phase 2 to improve connections from I-5 and I-90 to
24 the waterfront.
- 25 • Funding for the Spokane Street Viaduct Widening Project, which includes
26 a new Fourth Avenue S. off-ramp for West Seattle commuters.
- 27 • Added bus service in the West Seattle, Ballard/Uptown, and Aurora
28 Avenue corridors during the construction period, as well as a bus travel
29 time monitoring system.
- 30 • New traffic technology on SR 99 and major routes leading to SR 99 to keep
31 people and goods moving.
- 32 • Upgraded traffic signals and driver information signs for the Elliott
33 Avenue W./15th Avenue W., south of downtown, and West Seattle
34 corridors to support transit and traffic flow.
- 35 • Information about travel alternatives and incentives to encourage use of
36 transit, carpool, and vanpool programs.

1 Many of these build upon projects already underway by King County and the
2 City of Seattle to fully fund critical projects and advance elements of Metro's
3 RapidRide services. Transit enhancements and improvements to the street
4 system will play a major role in keeping people and goods moving during
5 construction of the S. Holgate Street to S. King Street Viaduct Replacement
6 Project, starting in 2010. These improvements will remain useful to travelers
7 during construction of the Bored Tunnel Alternative.

8 In addition to the Transportation Improvements to Minimize Traffic Effects
9 During Construction and the transit-related projects, more localized mitigation
10 measures will be developed as construction details are refined. Some localized
11 construction mitigation measures specific to this project might include the
12 following:

- 13 • Construction of temporary signals.
- 14 • Providing flaggers at certain intersections to facilitate both freight and
15 general purpose traffic movements.

16 In addition, the contractor selected to construct the project will be required to
17 prepare a traffic management plan, to be approved by the City of Seattle, to
18 ensure that construction effects on local streets, property owners, and businesses
19 are minimized. The traffic management plan will include at a minimum the
20 following measures:

- 21 • Details on required street and lane closures (duration and timing).
- 22 • Proposed detours and signing plans (for vehicles, pedestrians, freight, and
23 bicycles).
- 24 • Measures to minimize impacts on transit operations and access to/from
25 transit facilities (in coordination with transit service providers).
- 26 • Traffic enforcement measures, including deployment of police officers.
- 27 • Coordination with emergency service providers.
- 28 • Measures to minimize traffic and parking impacts from construction
29 employees.
- 30 • Measures to minimize effects of truck traffic for equipment and material
31 delivery.
- 32 • Measures to minimize disruption of access to businesses and properties.
- 33 • Measures to minimize conflicts between construction activities and traffic
34 during events. (This may or may not include stopping construction
35 activities during certain hours.)
- 36 • Public outreach communication plan.

Chapter 7

***Note to reviewers:** Chapter 7 includes evaluation of the BAT lanes north of Roy Street as part of the 2030 Program. Text discussing this is highlighted in yellow. In the next version of this report, the 2030 Program results (highlighted sections) will be discussed qualitatively in less detail. This discussion should include some selected quantitative results, and to that end please use this review cycle to decide what those will be.*

The project proposes to replace SR 99 from approximately S. Royal Brougham Way to Roy Street and remove the existing viaduct from approximately S. King Street to the Battery Street Tunnel. The project complements a number of other independent projects that improve safety and mobility along SR 99 and the Seattle waterfront, from the SODO area south of downtown to Seattle Center. Collectively, these individual projects are often referred to as the Program. This collection of projects is categorized into four groups: roadway elements, non-roadway elements, projects under construction, and completed projects. The cumulative effects of the Program are described in Section 7.1. The analysis of comprehensive cumulative effects in Section 7.2 includes the combined effect of the project (proposed action), other Program elements, and other projects that are anticipated to add to the transportation effects in the study area. Section 7.3 discusses cumulative effects during construction.

7.1 Cumulative Effects of the Program

Assessment of the cumulative effects of the Program includes an assessment of the proposed action plus Program elements that are not part of the proposed action. This section discusses the same performance measures as those in Section 5.1, but with a focus on the differences between the Program and the proposed action.

The following scenarios are compared in this section:

- 2015 Project (Bored Tunnel Alternative) compared to 2015 Partial Program (Bored Tunnel Alternative plus all Program elements except First Avenue Streetcar and King County Metro transit improvements) and 2015 Program (Bored Tunnel Alternative plus all Program elements).
- 2030 Project (Bored Tunnel Alternative) compared to 2030 Program.

The Program and Partial Program elements are described below. They are categorized into roadway elements and non-roadway elements. All of the elements are included in both the Program and the Partial Program unless otherwise noted.

1 **Roadway Elements**

2 Alaskan Way Surface Street Improvements

3 The Alaskan Way surface street would be rebuilt and improved between S. King
4 Street and Pine Street. The new surface street would be six lanes wide between
5 S. King and Columbia Streets (not including turn lanes), five lanes (two lanes
6 southbound and three lanes northbound) between Columbia and Marion Streets,
7 and four lanes between Marion and Pike Streets. Generally, the new street would
8 be located east of the existing street where the viaduct is located today. The new
9 street would include sidewalks, bicycle lanes, parking/loading zones, and
10 signalized pedestrian crossings at cross streets. The existing waterfront streetcar
11 would be replaced by a new streetcar line running on First Avenue. The new
12 surface street would provide a regional truck route for freight traveling to/from
13 the Duwamish/Harbor Island/SR 519 area and the BINMIC.

14 Elliott/Western Connector

15 The Elliott/Western Connector would provide a connection from the Alaskan
16 Way surface street to the Elliott/Western corridor that provides access to/from
17 BINMIC and neighborhoods north of Seattle (including Ballard and Magnolia).
18 The connector would be four lanes wide and would provide a grade-separated
19 crossing of the BNSF mainline railroad tracks. Additionally, it would provide
20 local street access to Pike Street and Lenora Street and integrate back into the
21 street grid at Bell Street, which would improve local street connections in
22 Belltown. The new roadway would include bicycle and pedestrian facilities.

23 Mercer Street West Corridor Improvements

24 The Mercer Street west corridor improvements include reconfiguring Mercer
25 Street between Fifth Avenue N. and Elliott Avenue to accommodate two-way
26 traffic. The route would be redesignated by the City as a regional truck route to
27 provide vital freight connections to Ballard/Interbay. These improvements would
28 provide access to Ballard/Interbay freight, as well as general traffic coming from
29 Ballard and Magnolia.

30 **Non-Roadway Elements**

31 First Avenue Streetcar

32 Functioning as a local connector, the First Avenue Streetcar would circulate
33 between S. Jackson Street and Republican Street. This alignment would travel
34 within several of Seattle's densest neighborhoods, including Pioneer Square, the
35 Commercial Core, Belltown, and Uptown. Additionally, it would serve many
36 tourist and regional attractions, such as Pike Place Market, Seattle Waterfront
37 Piers, Seattle Art Museum, Seattle Aquarium, and Olympic Sculpture Park. The
38 First Avenue Streetcar is not included in the 2015 Partial Program scenario.

1 Transit Enhancements

2 A variety of transit enhancements will be provided to support planned
3 transportation improvements associated with the Program. Development of the
4 specific improvements is underway. These transit enhancements are not included
5 in the 2015 Partial Program scenario.

6 Seawall Replacement

7 The Alaskan Way Seawall Replacement Project is a rehabilitation effort to protect
8 the shoreline along Elliott Bay, including Alaskan Way, from seawall failure due
9 to seismic and storm events. The project limits extend from S. Washington Street
10 in the south to Broad Street in the north.

11 Alaskan Way Promenade

12 A new expanded promenade and public space would be provided to the west of
13 the new Alaskan Way surface street between S. King Street and Pike Street. The
14 promenade would vary in width and would serve Piers 48 through 59, which
15 have varying uses including cruise ship and ferry terminals, restaurants, retail
16 shops, hotels, and regional entertainment, such as the Seattle Aquarium. Access
17 to the piers would be provided by service driveways.

18 Between Marion and Pike Streets, the promenade would be approximately 70 to
19 80 feet wide. This public space will be designed at a later date. Other potential
20 open spaces include a triangular space north of Pike Street and east of Alaskan
21 Way, and parcels created by the removal of the viaduct between Lenora and
22 Battery Streets.

23 **Projects Under Construction**

24 S. Holgate Street to S. King Street Viaduct Replacement Project

25 The S. Holgate Street to S. King Street Viaduct Replacement Project will replace
26 this seismically vulnerable portion of SR 99 with a seismically sound structure
27 that is designed to current roadway and safety standards. An Environmental
28 Assessment for this project was completed in June 2008, and the Finding of No
29 Significant Impact was published in February 2009. Construction began in mid-
30 2009 with early utility relocations and is expected to be completed at the end of
31 2014. This project is included in the Baseline.

32 **Transportation Improvements to Minimize Traffic Effects during Construction**

33 There are several transportation improvements that are underway to help offset
34 traffic effects during construction of the projects included in the Program.
35 Construction or implementation of these improvements is underway and
36 includes the following:

- 1 • Adding variable speed signs and travel time signs on I-5 to help maximize
2 safety and traffic flow.
- 3 • Providing funding for the Spokane Street Viaduct Widening Project,
4 which includes a new Fourth Avenue S. off-ramp for West Seattle
5 commuters.
- 6 • Adding buses and bus service in the West Seattle, Ballard/Uptown, and
7 Aurora Avenue corridors during construction, as well as a bus travel time
8 monitoring system.
- 9 • Upgrading traffic signals and driver information signs for the Denny Way,
10 Elliott Avenue W./15th Avenue W., south of downtown, and West Seattle
11 corridors to support transit and traffic flow.
- 12 • Providing information about travel alternatives and incentives to
13 encourage use of transit, carpool, and vanpool programs.

14 7.1.1 Regional Context and Travel Patterns

15 Vehicle Miles of Travel

16 Key Findings

- 17 • There is little difference in VMT among the 2015 Project, Partial Program,
18 and Program scenarios for the Seattle Center City area, although there is a
19 marginal decrease from the 2015 Project and Partial Program to the 2015
20 Program. This is likely due to the conversion of a general purpose lane to
21 a BAT lane in each direction on SR 99 north, which creates a bottleneck for
22 general purpose traffic and reduces projected travel on SR 99 in the Center
23 City area. This pattern generally holds true for the four-county Puget
24 Sound region as well.
- 25 • Percentage growth in VMT (from 2015 to 2030) is higher outside of the
26 Seattle Center City area despite the higher growth rates in jobs and
27 population. This is likely due to the disproportionately higher number of
28 trips to/from downtown that are expected to be accommodated by transit
29 in the future as compared to the rest of the region.

30 VMT for the 2015 and 2030 scenarios is shown in Exhibit 7-1.

31 As shown in Exhibit 7-1, for the Seattle Center City area during the AM and PM
32 peak period, the 2015 Project, Partial Program, and Program scenarios show
33 approximately the same level of VMT, with a marginal decrease in the full
34 Program. This decrease is likely due to the conversion of a general purpose lane
35 to a BAT lane in each direction on SR 99 between Aloha Street and just south of
36 the Aurora Bridge. This conversion creates a bottleneck for general purpose
37 traffic and reduces projected travel on SR 99, forcing trips outside of the Center

1 City area. Due to growth in population and employment, both the 2030 Project
 2 and Program scenarios during the AM and PM peak periods show increases in
 3 VMT of about 4 to 5 percent over comparable 2015 Project and Program levels.
 4 Daily VMT levels increase for both the 2030 Project and Program scenarios by
 5 about 5 percent over the comparable 2015 scenarios.

6 **Exhibit 7-1. Vehicle Miles of Travel**

Performance Measure	2015			2030	
	Project	Partial Program	Program	Project	Program
Seattle Center City					
AM	416,000	416,600	414,300	432,300	430,900
PM	516,000	516,400	512,900	541,300	538,900
Daily	2,342,900	2,342,300	2,330,600	2,463,600	2,452,700
Four-County Region					
AM	15,799,100	15,787,500	15,797,900	17,665,800	17,667,500
PM	18,558,000	18,566,600	18,556,400	20,831,900	20,844,100
Daily	84,754,100	84,759,000	84,746,800	94,955,300	94,995,600

7
 8 In looking at the four-county region, there is no meaningful difference in VMT
 9 among the 2015 scenarios and among the 2030 scenarios. In general, for all time
 10 periods, VMT for the 2030 Project and Program scenarios increases by about
 11 12 percent over the comparable 2015 Project and Program scenarios. Despite the
 12 fact that population and employment are expected to grow at a faster rate in the
 13 Center City area in comparison to the four-county region as a whole, the 2015 to
 14 2030 VMT growth rate for the four-county region is higher than that of the
 15 comparable Center City growth rate (about 4 to 5 percent). This is likely due to
 16 the increased use of transit for travel to/from the Center City area in the future,
 17 which allows the accommodation of more trips in relatively fewer vehicles.

18 **Vehicle Hours of Travel**

19 Key Findings

- 20 • There is no meaningful difference in VHT among the 2015 Project, Partial
 21 Project, and Program scenarios for the Center City area. This pattern also
 22 holds true for the four-county Puget Sound region.
- 23 • While percentage growth in VHT (from 2015 to 2030) is higher outside of
 24 the Center City, which is similar to the VMT pattern, VHT growth,
 25 percentage-wise, is more pronounced than what was seen for VMT. This
 26 is likely the result of greater increase in congestion in suburban
 27 communities than on Seattle streets, which are already heavily congested

1 during peak travel periods, as well as an increased emphasis on transit
2 to/from the Center City area.

3 VHT for the 2015 and 2030 scenarios is shown in Exhibit 7-2.

4 **Exhibit 7-2. Vehicle Hours of Travel**

Performance Measure	2015			2030	
	Project	Partial Program	Program	Project	Program
Seattle Center City					
AM	16,500	16,300	16,300	18,000	17,900
PM	23,600	23,300	23,500	29,600	29,800
Daily	84,300	83,500	83,700	96,600	96,300
Four-County Region					
AM	616,400	613,500	616,100	945,600	951,000
PM	698,700	699,000	699,800	1,037,500	1,044,700
Daily	2,571,000	2,568,400	2,571,900	3,532,500	3,547,800

5

6 As shown in Exhibit 7-2, for the Seattle Center City area during the AM and PM
7 peak period, the 2015 Project, Partial Program, and Program scenarios show
8 approximately the same level of VHT. Due to growth in population and
9 employment, both the 2030 Project and Program for the AM and PM peak period
10 show increases in VHT of about 4 to 5 percent over the comparable 2015 Project
11 and Program levels. Daily VHT levels increase for both the 2030 Project and
12 Program scenarios by about 5 percent over the comparable 2015 scenarios.

13 In looking at the four-county region, there is no meaningful difference in VHT
14 among the 2015 scenarios and among the 2030 scenarios. Again, in comparing the
15 growth between 2015 and 2030, the growth in VHT, percentage-wise, is more
16 pronounced than what was seen for VMT, which could be caused by increased
17 delay due to more traffic congestion on regional streets and highways. For the
18 AM peak period, the 2030 Project and Program VHT increases by about
19 54 percent over that of the comparable 2015 Project and Program scenarios. For
20 the PM peak period, the 2030 Project and Program VHT increases about
21 49 percent over the comparable 2015 Project and Program scenarios. Daily VHT
22 growth between 2015 and 2030 for the above scenarios is about 38 percent.

23 **Vehicle Hours of Delay**

24 Key Findings

- 25 • There is no meaningful difference in VHD among the 2015 Project, Partial
26 Project, and Program scenarios for the Center City area. This pattern also
27 holds true for the four-county Puget Sound region.

- Again for the Center City area, the 2015 Partial Program shows a slight reduction in VHD, which could be the result of a greater congestion in the 2015 Program caused by the introduction of a BAT lane on Aurora Avenue. The BAT lane causes increased congestion in the adjacent general purpose lanes, inducing a slightly greater delay in the Program over the Partial Program scenarios.
- The growth in VHD (from 2015 to 2030) is higher percentage-wise than what was seen in the VHT results, because delay continues to be a growing problem throughout the Center City area and four-county Puget Sound region.
- By 2030, the higher growth in VHD, percentage-wise, is projected to occur outside the city of Seattle, reflecting the higher number of trips to/from downtown that are expected to be accommodated by transit in the future.

VHD for the 2015 and 2030 scenarios is shown in Exhibit 7-3.

Exhibit 7-3. Vehicle Hours of Delay

Performance Measure	2015			2030	
	Project	Partial Program	Program	Project	Program
Seattle Center City					
AM	5,700	5,500	5,600	6,800	6,700
PM	10,000	9,700	10,000	15,100	15,400
Daily	24,500	23,900	24,300	33,200	33,300
Four-County Region					
AM	254,200	251,600	253,900	531,500	536,900
PM	272,800	273,000	274,000	548,100	555,000
Daily	680,200	677,800	681,400	1,370,400	1,384,900

As shown in Exhibit 7-3, forecasts of total VHD in the Seattle Center City area remain relatively constant for all the 2015 scenarios for all time periods. However, the Partial Program generally shows slightly decreased VHD than the other scenarios, including the full 2015 Program. One of the reasons the 2015 Program shows greater delay than the 2015 Partial Program is the greater congestion in the Program caused by the introduction of the BAT lane on Aurora Avenue between Aloha Street and just south of the Aurora Bridge. This BAT lane creates a bottleneck where the SR 99 mainline is reduced from three to two general purpose lanes. The expected result is increased congestion in the general purpose lanes along SR 99 leading up to this segment, inducing greater delay over the Partial Program scenario, which does not include the BAT lane.

For the four-county Puget Sound region, there is no meaningful difference in VHD among the 2015 scenarios and among the 2030 scenarios during all time

1 periods. In comparing 2015 and 2030, the growth in VHD, percentage-wise, is
 2 more pronounced than what was seen for VHT, which could be the result of more
 3 traffic encountering more congested road conditions, particularly in the growing
 4 urban centers outside of the Center City area. For the AM peak period, the 2030
 5 Project and Program VHD increases by about 110 percent over the comparable
 6 2015 Project and Program scenarios. For the PM peak period, the 2030 Project and
 7 Program VHD increases by about 102 percent over the comparable 2015 Project
 8 and Program scenarios. The increase in daily VHT between 2015 and 2030 for the
 9 above scenarios is also about 102 percent. In looking at the Center City area, the
 10 increase in VHD between 2015 and 2030 is less pronounced than the full region.
 11 This is likely because a higher number of trips to/from downtown are expected to
 12 be accommodated by transit in the future in comparison to the region as a whole.

13 **Screenline Vehicle Volumes**

14 To evaluate cumulative effects on parallel streets and highways, AM and PM
 15 peak period and daily traffic volumes were assessed for the 2015 Project, 2015
 16 Partial Program, 2015 Program (full), 2030 Project, and 2030 Program scenarios.
 17 The same six screenlines evaluated in Chapter 5 were used in this assessment.
 18 Exhibit 7-4 provides a comparison of the screenline totals by scenario (by time
 19 period) for the four Center City screenline locations.

20 **Exhibit 7-4. Model-Estimated Vehicle Volumes at Screenlines**

Performance Measure	2015			2030	
	Project	Partial Program	Program	Project	Program
Spokane Street Screenline (North of S. Spokane Street)					
AM Peak Hour	33,000	33,060	33,000	34,660	34,700
PM Peak Hour	37,770	36,680	36,730	38,580	38,650
Daily	468,900	469,800	469,000	497,600	498,000
South Screenline (South of S. King Street)					
AM Peak Hour	36,100	36,200	36,100	37,500	37,700
PM Peak Hour	42,100	42,400	42,200	43,600	43,900
Daily	536,800	539,000	537,600	561,600	563,800
Central Screenline (North of Seneca Street)					
AM Peak Hour	32,900	33,100	33,000	34,100	34,200
PM Peak Hour	36,800	37,200	37,000	37,900	38,100
Daily	440,400	442,500	440,400	453,900	457,000
North Screenline (North of Thomas Street)					
AM Peak Hour	39,400	38,600	38,300	40,700	40,000
PM Peak Hour	43,700	42,900	42,700	46,400	45,200
Daily	523,600	509,900	506,700	558,600	542,200

21

1 Exhibits 7-5 and 7-6 graphically compare daily volumes for the 2015 and 2030
2 Project versus Program scenarios at key locations on SR 99, I-5, and Alaskan Way
3 and across selected screenlines for arterial volumes (i.e., these screenlines do not
4 include SR 99 or I-5 volumes) at locations generally similar to the four
5 summarized in tabular format.

6 Two screenlines, measuring volumes traveling east and west near Aurora Avenue
7 in north Seattle, as outlined in Chapter 5, were also evaluated. Exhibit 7-7 shows
8 these volumes graphically.

9 Key Findings

- 10 • The Spokane Street, south, and central screenline totals are fairly
11 consistent across all the 2015 and 2030 scenarios. However, volumes
12 across the screenline in the north are expected to decrease somewhat in
13 the Program scenarios due to the conversion of a general purpose lane to a
14 BAT lane on Aurora Avenue and the resulting capacity constraint on
15 general purpose traffic.
- 16 • Growth in screenline volumes between the 2015 and 2030 scenarios is
17 generally marginal because streets and highways are already congested
18 for many hours of the day and more trips are expected to be
19 accommodated by transit to/from and within the Center City area in the
20 future.
- 21 • Provision for the Elliott/Western Connector for all three Program scenarios
22 improves connectivity and access for Alaskan Way traffic, thus attracting
23 higher demand on this facility in the Program scenarios as opposed to the
24 Project scenarios.
- 25 • Vehicle volumes on east-west arterials north of the Ship Canal have very
26 minor differences across all scenarios for 2015 and 2030, indicating that the
27 differences in the roadway networks provided by the Program versus the
28 Project scenarios do not affect east-west travel north of the Ship Canal.

29 Spokane Street Screenline

30 The Spokane Street screenline volumes are extremely consistent across all
31 scenarios for the 2015 and 2030 time periods as shown in Exhibit 7-4. The growth
32 in volume from 2015 to 2030 for all scenarios was 5 percent in the peak periods
33 and 6 percent daily. This relatively low growth in vehicle trips is reflective of the
34 higher transit use to/from downtown Seattle expected in the future, and the
35 already high utilization of roadway capacity in the 2015 scenarios, which limits
36 the amount of traffic growth that can occur. Daily traffic on the arterials shows
37 the same pattern on this screenline as that shown in Exhibit 7-6, as does the
38 projected volumes on SR 99 (Exhibit 7-5).

This Page Intentionally Left Blank

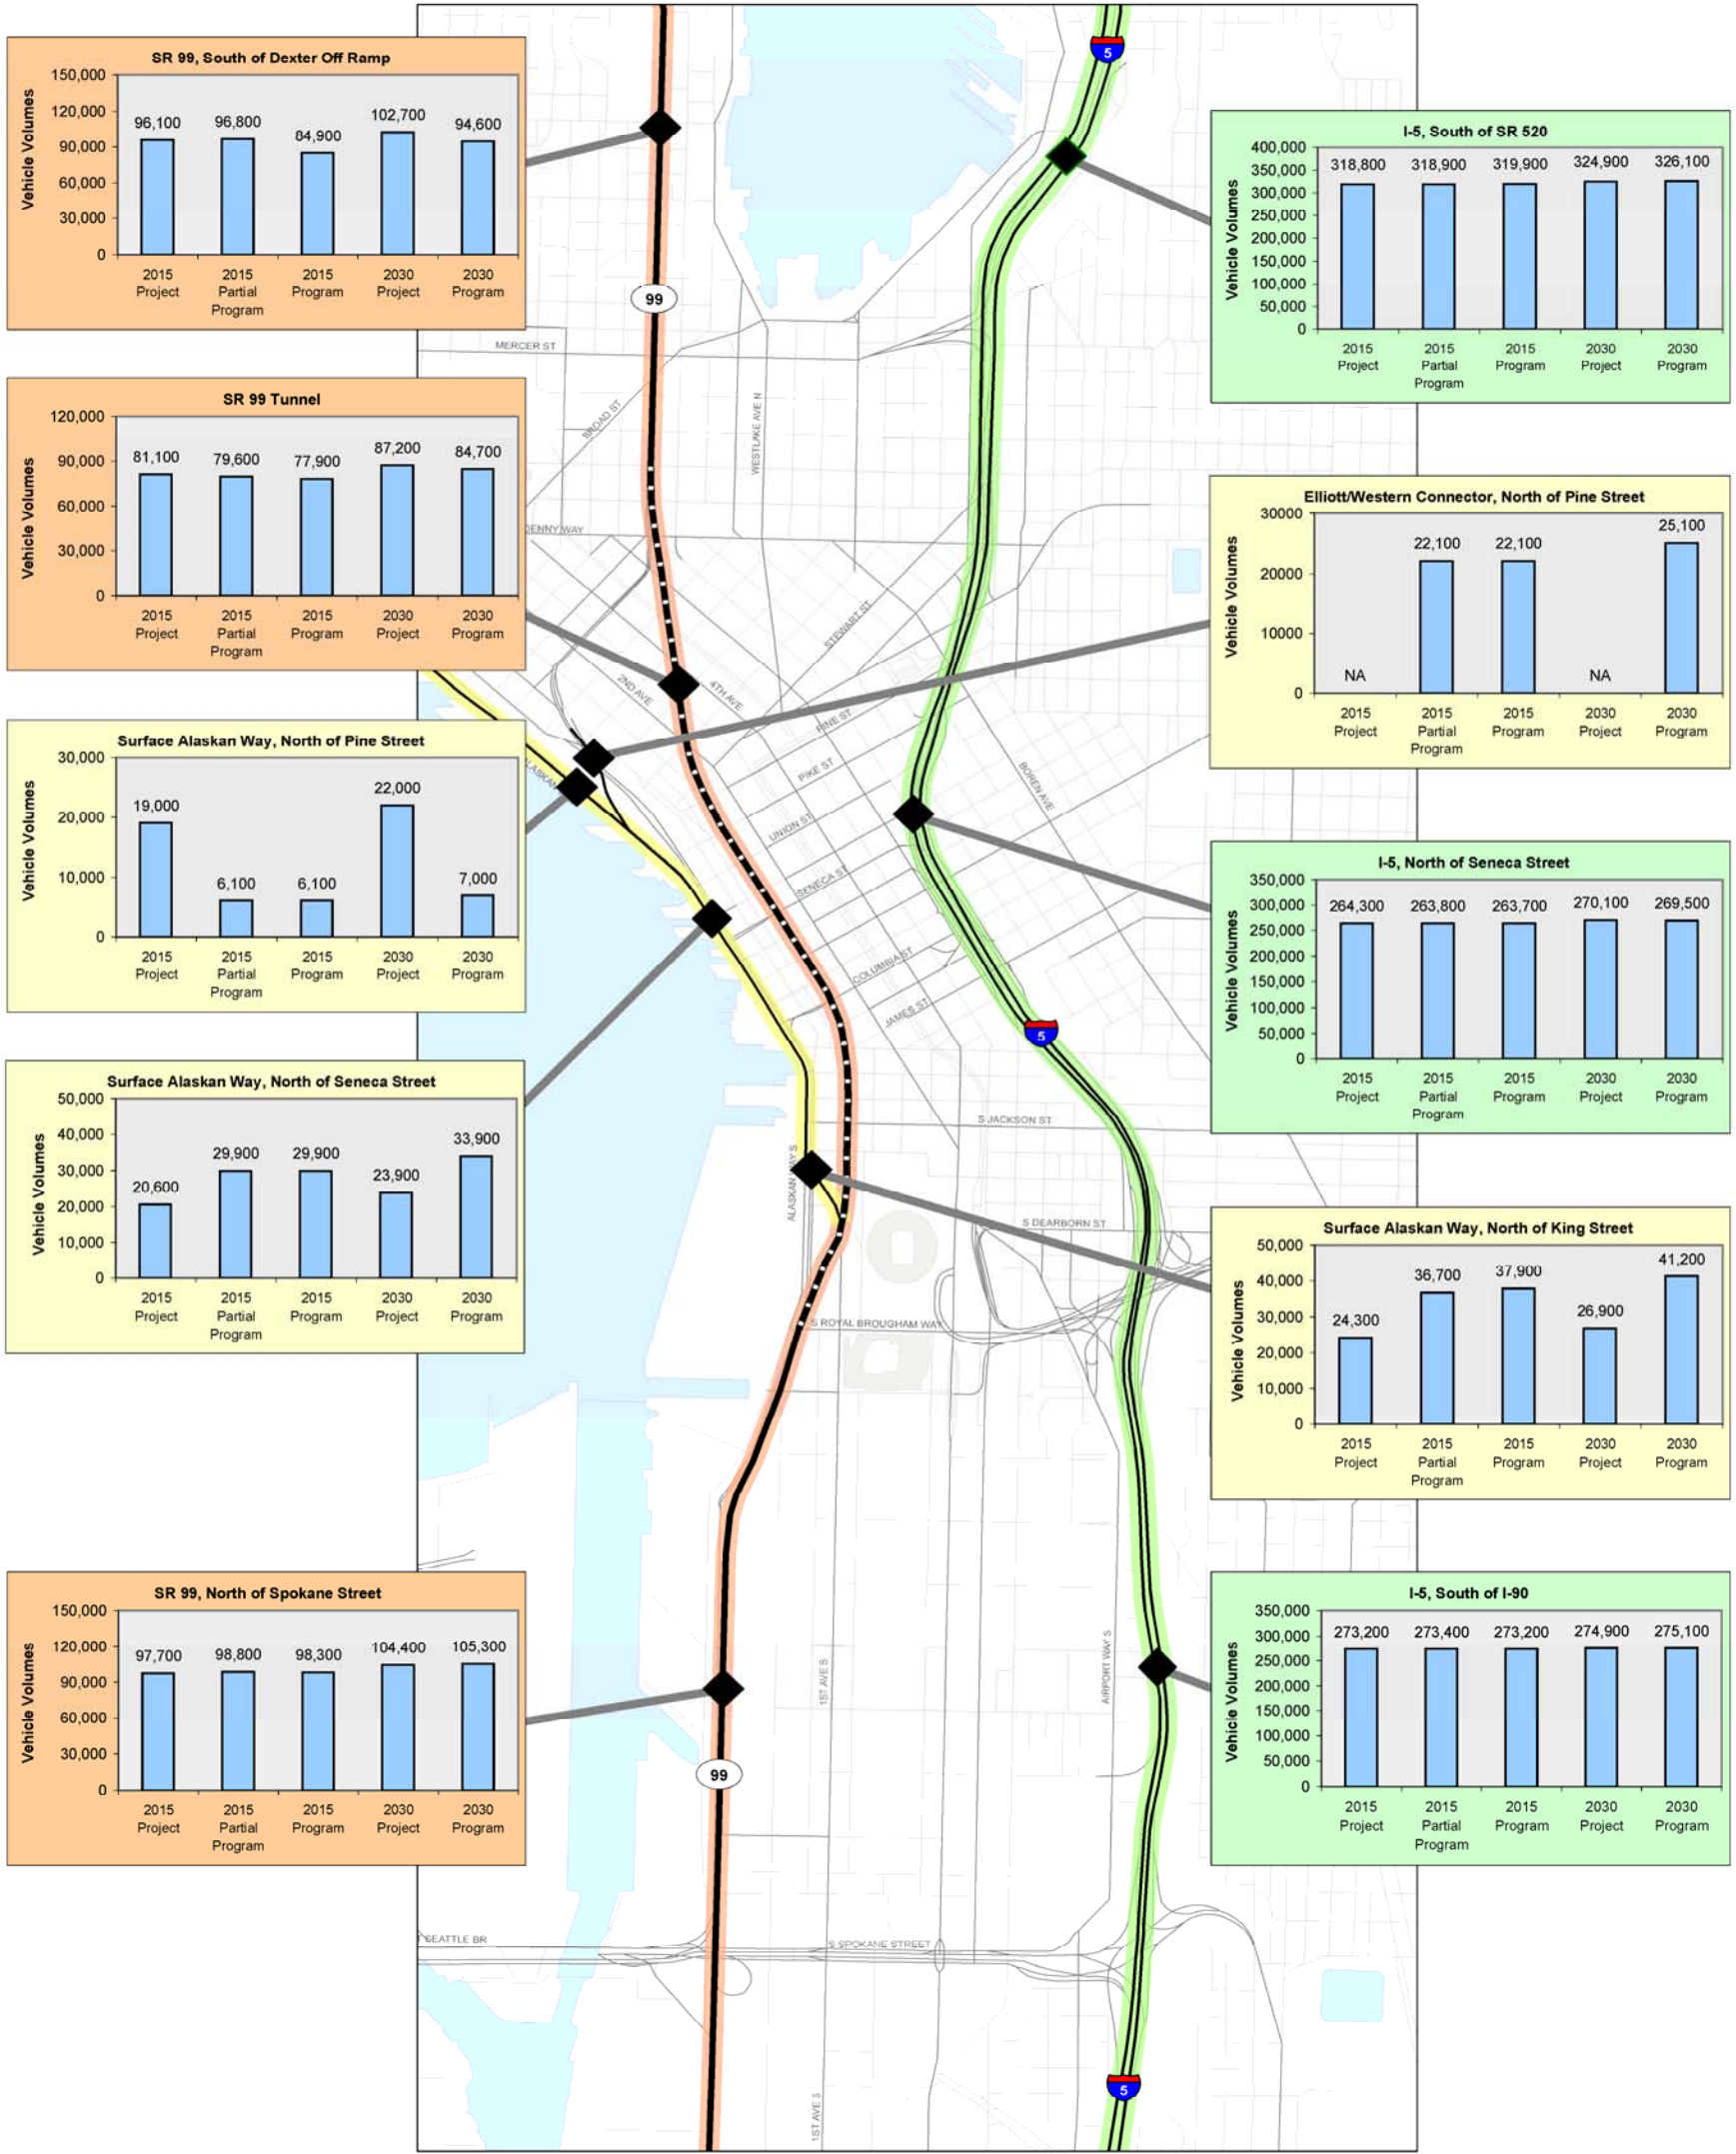

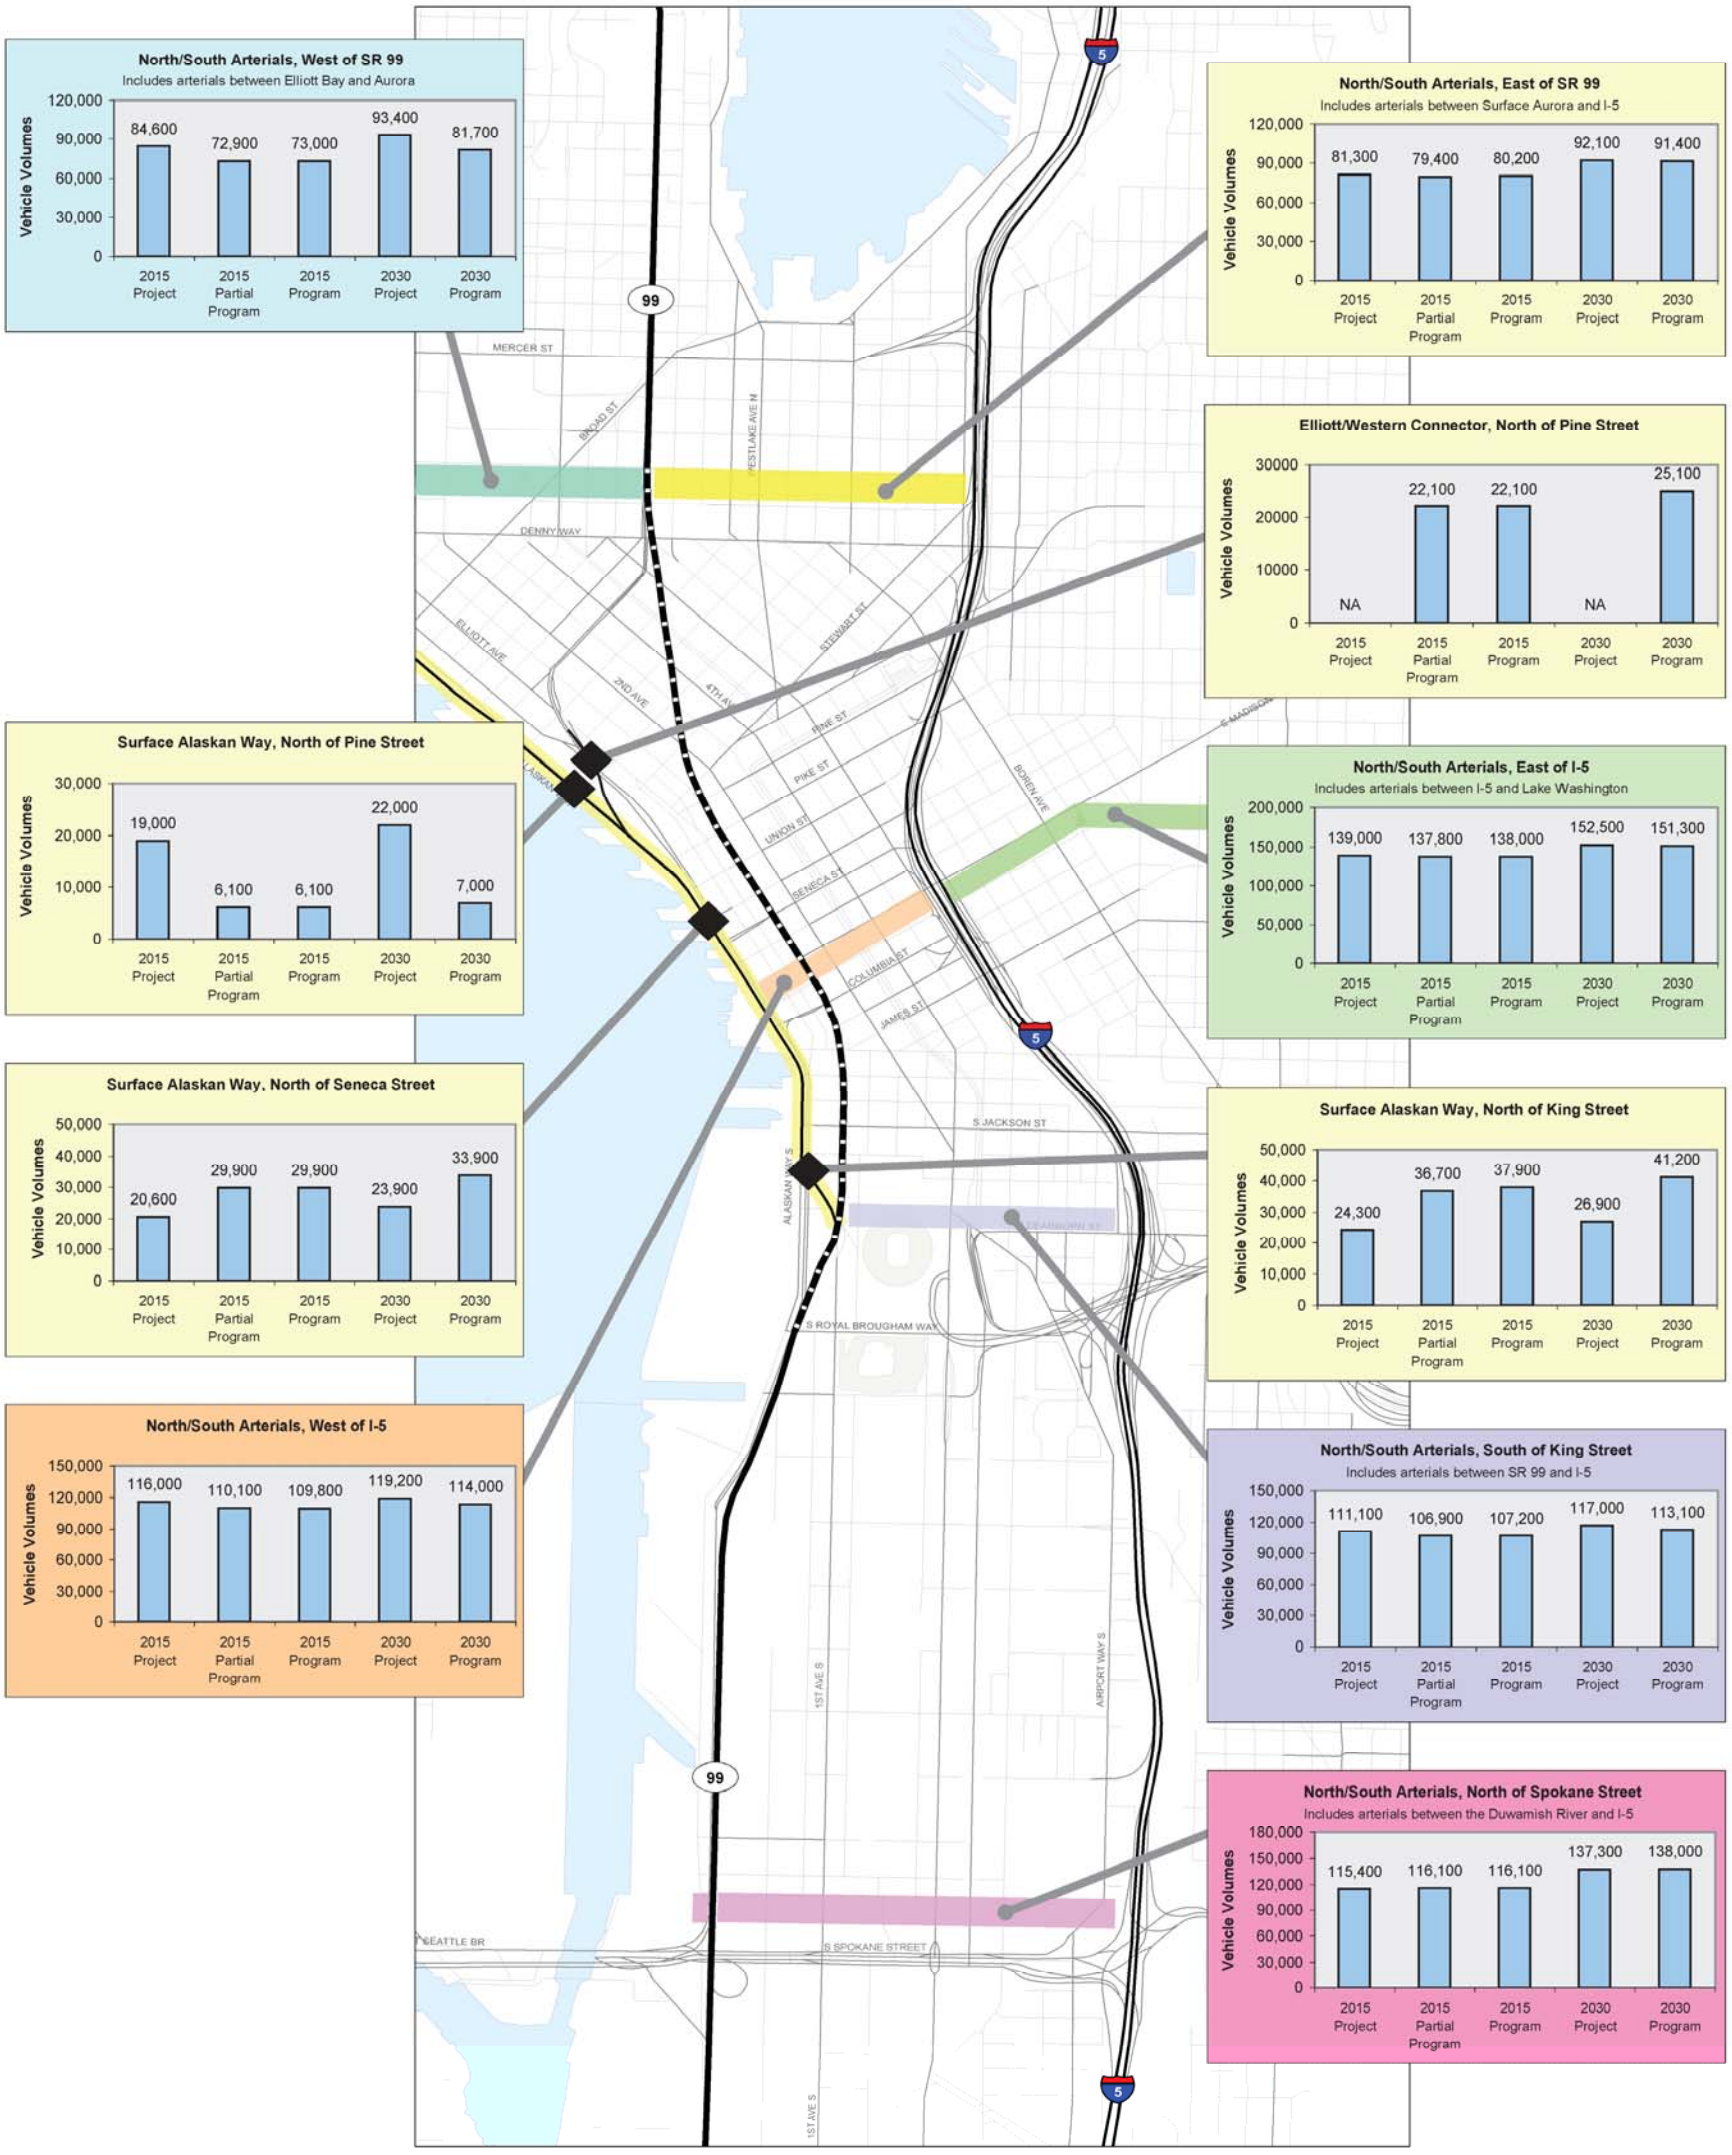

Exhibit 7-5
Daily Vehicle Volumes on I-5, SR 99 and Alaskan Way
for 2015 Project, 2015 Partial Program, 2015 Program,
2030 Project and 2030 Program

Arterial screenlines do not include I-5 or SR 99 volumes

Exhibit 7-6
Daily Vehicle Volumes on Arterials for 2015 Project,
2015 Partial Program, 2015 Program, 2030 Project and
2030 Program

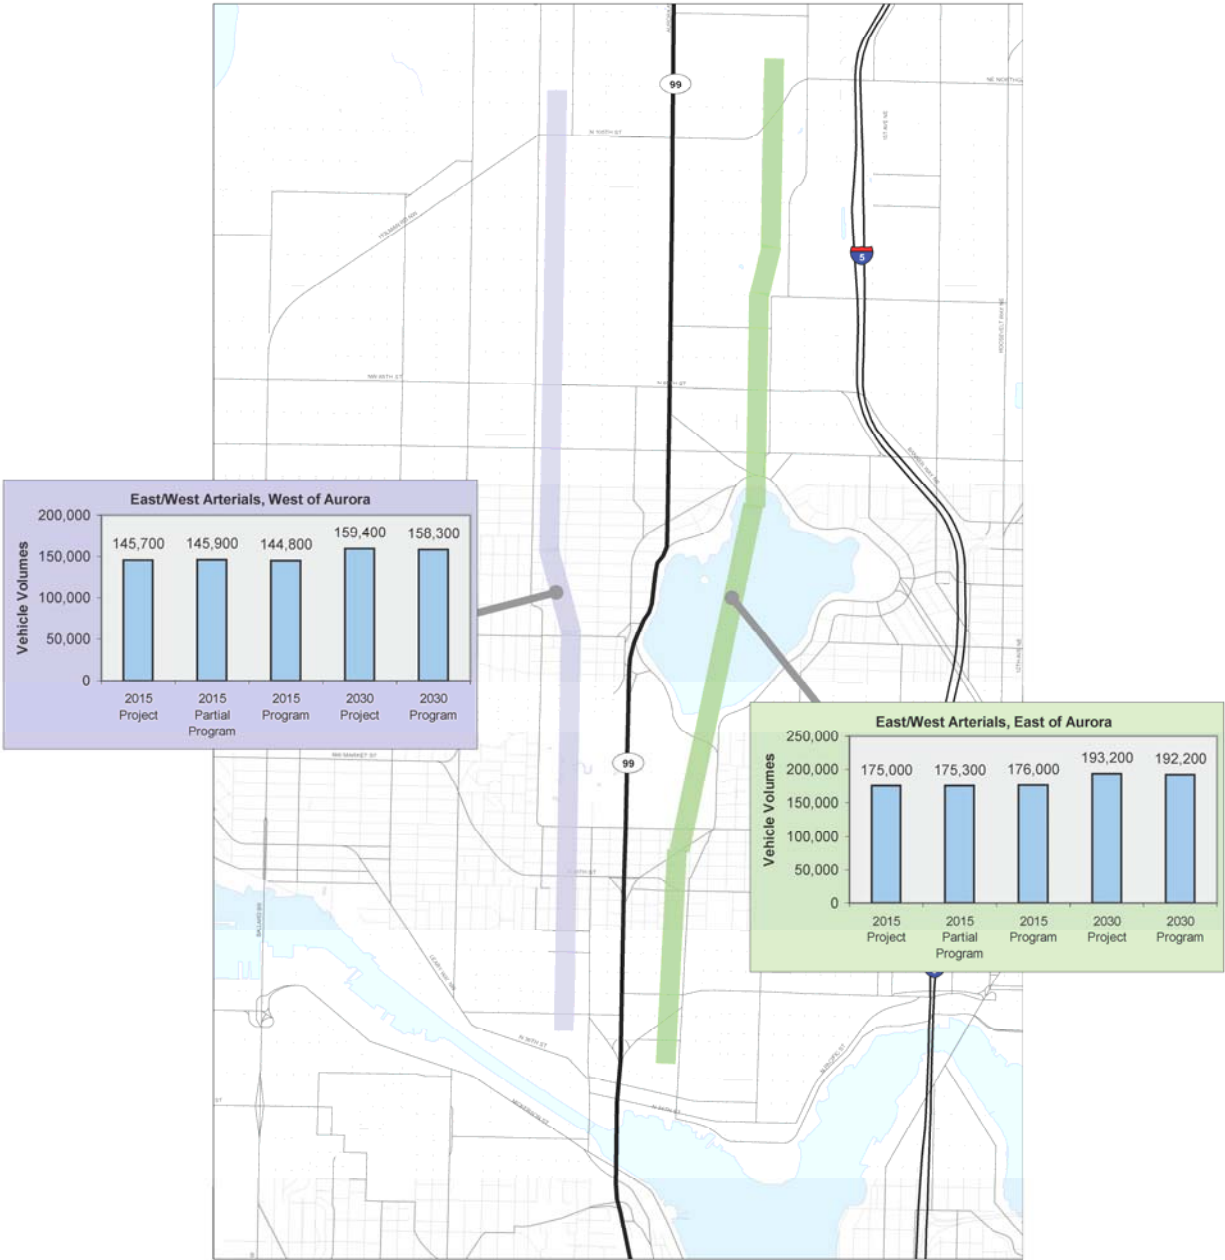

Exhibit 7-7
Daily Vehicle Volumes on Arterials in
North Seattle for 2015 Project, 2015
Partial Program, 2015 Program, 2030
Project and 2030 Program

1 Since the Spokane Street screenline is farther from the cumulative effects elements
2 in the Program scenarios, the volume differences between Project and Program
3 scenarios in 2015 and 2030 are all very minor.

4 South Screenline

5 Similar to the Spokane Street screenline, as shown in the table in Exhibit 7-4, the
6 vehicle volumes at the south screenline are fairly consistent across all the 2015
7 scenarios (Project, Partial Program, and Program) for all time periods. The same
8 can also be said for the 2030 Project and Program scenarios. Growth in
9 screenlines between 2015 and 2030 is generally marginal, as volumes for the 2030
10 Program are about 4 to 5 percent higher than the comparable 2015 Program
11 scenario, regardless of time period. As with the Spokane Street screenline, the
12 limited growth is due in part to increased transit usage and high utilization of
13 roadway capacity. Growth in volumes for the 2030 Project scenario over the
14 comparable 2015 Project scenario is slightly lower percentage-wise than the
15 Program scenario (2015-2030). Increases in volume at this screenline ranges from
16 about 3.5 to a little over 4 percent, regardless of time period. The reason that
17 volumes between 2015 and 2030 in the Program grow slightly more than volumes
18 in the Project is likely because the Elliott/Western Connector along with the
19 enhanced Alaskan Way along the waterfront provide the Program with a little
20 more capacity to grow as compared to the Project.

21 As shown in the graphic in Exhibit 7-6, individual streets can fluctuate greatly
22 depending on the effects of certain scenarios regardless of the total volume across
23 the entire screenline. A case in point is Alaskan Way both south of S. King Street
24 and north of Seneca Street. In these locations, under the 2015 and 2030 Project
25 scenarios, daily volumes are significantly lower than the 2015 Partial Program,
26 Program, and 2030 Program scenarios. The higher capacity waterfront boulevard
27 as well as the inclusion of the Elliott/Western Connector in the respective
28 Program scenarios helps to improve capacity, connectivity, and access to the
29 central waterfront and Alaskan Way, which attracts higher demand at this
30 location. As seen in Exhibit 7-5, for the north-south arterials along the south
31 screenline between SR 99 and I-5, the three Program scenarios (2015 Partial
32 Program, 2015 Program, and 2030 Program), all show slightly lower volumes than
33 the comparative Project scenarios. The reason these vehicle volumes are lower is
34 the fact that Alaskan Way, which is not included in this screenline, is attracting
35 more traffic in the Program scenarios, reducing volumes that enter, exit, or travel
36 through downtown via other arterials.

37 Central Screenline

38 Like the results for the Spokane Street and south screenlines, the vehicle volumes
39 at the central screenline (Exhibit 7-4) are fairly consistent across all the 2015

1 scenarios (Project, Partial Program, and Program) for all time periods. The same
2 can also be said for the 2030 Project and Program scenarios. Growth in
3 screenlines between 2015 and 2030 is generally marginal, as volumes for both the
4 2030 Project and Program are about 3 to 4 percent higher than the comparable
5 2015 scenarios, regardless of time period.

6 Like the Spokane Street and south screenlines, the three Program scenarios all
7 show slightly lower volumes than the Project scenarios for north-south arterials
8 west of I-5 (see Exhibit 7-5). Again, the reason these vehicle volumes are lower is
9 the fact that Alaskan Way, which is not included in the screenline, is attracting
10 more traffic in the Program scenarios, reducing volumes that enter, exit, or travel
11 through downtown via other arterials. For north-south arterials east of I-5
12 though, the difference between the Project and Program scenarios is minimal, as
13 the scenarios have much less impact in this area. Also, vehicle volumes on I-5
14 near the central screenline (see Exhibit 7-6) are generally the same regardless of
15 scenario, as I-5 is at capacity many hours of the day and cannot absorb large
16 increases in demand. Note that projected daily volumes on SR 99 through the
17 bored tunnel (see Exhibit 7-5) are slightly less in the 2015 Partial Program as
18 compared to the 2015 Project. This is likely due to the addition of the Elliott/
19 Western Connector and the enhanced waterfront along Alaskan Way in the
20 Program that attracts more of the Elliott/Western trips away from the Mercer
21 Street/bored tunnel route in the Project.

22 The bored tunnel volume for the 2015 Program is projected to be lower than that
23 of the Partial Program primarily because of the conversion of a general purpose
24 lane to a BAT lane on SR 99 north between Aloha Street and the Aurora Bridge.
25 This conversion creates a bottleneck for general purpose traffic and effectively
26 constrains the volumes that can access the tunnel. The bored tunnel volumes in
27 the 2030 Program as compared to the 2030 Project show the same pattern for the
28 same reason.

29 North Screenline

30 Continuing the trend shown in the Spokane Street, south, and central screenlines,
31 the vehicle volumes at the north screenline (Exhibit 7-4) are fairly consistent
32 across all the 2015 scenarios (Project, Partial Program, and Program) for all time
33 periods. The same can also be said for the 2030 Project and Program scenarios.
34 Growth in screenlines between 2015 and 2030 is slightly higher than what was
35 reflected in the south and central screenlines, which could be the result of higher
36 population and employment growth in the South Lake Union area. Vehicle
37 volumes for the 2030 Program are about 4.5 to 7 percent higher than the
38 comparable 2015 Program scenario, regardless of time period. Growth in
39 volumes for the 2030 Project scenario over the comparable 2015 Project scenario is

1 slightly lower percentage-wise than the Program scenario (2015-2030). Increases
2 in volume at this screenline range from over 3 to 6.5 percent, regardless of time
3 period.

4 The differences among the scenarios with respect to growth in arterial traffic
5 volume become more pronounced at the north screenline (see Exhibit 7-5).
6 Similar to the south and central screenlines, fewer vehicles on north-south
7 arterials west of Aurora Avenue (SR 99) cross the screenline under the 2015
8 Partial Program, 2015 Program, and 2030 Program in comparison to the
9 comparable Project scenarios. However, this result is primarily due to the
10 conversion of Mercer Street to two-way traffic between Fifth Avenue N. and
11 Elliott Avenue in the Program scenarios, which makes Mercer Street a more
12 attractive westbound route between SR 99 (and points east) and Elliott Avenue.
13 In the Project scenarios, many of these westbound trips instead traveled
14 southbound to Denny Way and then back north via Elliott Avenue, in many cases
15 crossing the screenline twice; hence resulting in higher screenline volumes than
16 those in the Program. Vehicle volumes on the east side of Aurora Avenue for the
17 year 2015 are relatively consistent, while in the 2030 Project and Program
18 scenarios, they increase about 13 percent likely due to growth in employment and
19 population in the South Lake Union area.

20 Projected volumes on SR 99 south of the Dexter Avenue southbound off-ramp are
21 similar between the 2015 Project and Partial Program but are 12 percent lower in
22 the 2015 Program due to the constraint caused by the conversion of a general
23 purpose lane to a BAT lane in this location. For similar reasons, the projected
24 2030 volumes at this location show the 2030 Program to be 8 percent lower than
25 the 2030 Project.

26 North Seattle

27 Vehicle volumes on east-west arterials north of the Ship Canal are similar across
28 all scenarios for all time periods. The small scale of these differences, all less than
29 1 percent, is due to the distance of these arterials from the locations of the projects
30 being evaluated for cumulative effects. In addition, it indicates that the
31 differences in the roadway networks provided by the Program versus the Project
32 scenarios do not affect east-west travel north of the Ship Canal.

33 **Person Throughput**

34 Person throughput was estimated for the 2015 Project, Partial Program, and
35 Program scenarios as well as the 2030 Project and Program scenarios for the same
36 key screenlines as those analyzed in Chapter 5.

1 Key Findings

- 2 • Both the Partial Program and Program scenarios carry a marginally higher
 3 number of persons in comparison to their respective Project scenarios.
 4 This is likely due to the increase in transit service provided in the Program
 5 scenarios and improved street connections provided in the Partial
 6 Program scenario.

7 Exhibit 7-8 presents the person-trips per day for the 2015 and 2030 Project and
 8 Program scenarios.

9 **Exhibit 7-8. Model-Estimated Daily Person Throughput (Person-Trips)**

Performance Measure	2015			2030	
	Project	Partial Program	Program	Project	Program
South Screenline (South of S. King Street)					
AM	54,000	54,300	54,500	65,400	65,700
PM	66,600	67,000	67,100	79,000	79,600
Daily	776,900	780,800	780,700	883,600	888,400
Central Screenline (North of Seneca Street)					
AM	52,300	52,600	52,700	60,400	60,800
PM	61,500	62,000	62,000	69,900	70,400
Daily	650,300	654,100	652,700	746,600	753,300
North Screenline (North of Thomas Street)					
AM	59,100	58,300	58,000	67,800	67,400
PM	70,000	69,000	68,900	80,800	79,600
Daily	760,800	743,900	740,200	866,700	847,700

10

11 In observing the ability of the street network to carry persons (as opposed to
 12 vehicles), each of the scenarios carry roughly the same amount of persons at the
 13 study area screenlines, regardless of time period.

14 For the south screenline, both the 2015 Partial Program and 2015 Program
 15 scenarios carry a marginally higher number of persons in comparison to the 2015
 16 Project scenario. This may be due to the increase in transit service and improved
 17 street connections provided in the Program scenario and Partial Program
 18 scenario.

19 The overall differences in person-trips among the 2015 scenarios are relatively
 20 small for the south and central screenlines. Refer to Exhibit 7-7 for a table of daily
 21 person trips. The north screenline shows higher daily person-trips for the 2015
 22 Project scenario in comparison to the 2015 Partial Program and 2015 Program.

1 Similar to the screenline vehicle trip volumes, this result is primarily due to the
2 conversion of Mercer Street to two-way traffic between Fifth Avenue N. and
3 Elliott Avenue in the Program scenarios, which makes Mercer Street a more
4 attractive westbound route between SR 99 (and points east) and Elliott Avenue.
5 In the Project scenarios, many of these westbound trips instead traveled
6 southbound to Denny Way and then back north via Elliott Avenue, in many cases
7 crossing the screenline twice; hence resulting in a higher number of screenline
8 person-trips than the number in the Program.

9 7.1.2 Traffic Operations on SR 99

10 Key Findings

- 11 • The 2015 Partial Program volume estimates are generally similar to the
12 2015 Project forecasts, with modest increases in volumes for most mainline
13 and ramp segments south of downtown, modest decreases in the bored
14 tunnel, and increases north of downtown.
- 15 • The 2030 Program volume estimates are generally similar to the 2030
16 Project forecasts, with modest increases in volumes for most mainline and
17 ramp segments south of downtown and modest decreases in the bored
18 tunnel and ramps in the South Lake Union area. The one exception to this
19 is a substantial decrease in both directions on the SR 99 mainline north of
20 downtown with the 2030 Program. This decrease is due to the conversion
21 of one lane in each direction to a BAT lane, which substantially reduces
22 the capacity of the mainline for general traffic.
- 23 • With implementation of the 2015 Partial Program, the mainline LOS is
24 projected to be similar to that projected for 2015 Project.
- 25 • The mainline LOS under the 2030 Program scenario is generally expected
26 to be similar to that projected for 2030 Project, with some improvement in
27 LOS in the south end of the project area and some decline in LOS in the
28 north end of the project area. Both changes in LOS between the 2030
29 Project and 2030 Program are mainly due to the decrease in mainline
30 capacity with the addition of the BAT lanes north of downtown, which is
31 expected to result in high levels of congestion. That congestion would
32 create a bottleneck that would reduce the number of vehicles served, such
33 that the southbound LOS would actually improve south of downtown due
34 to the reduced volume of vehicles. In the northbound direction, more
35 traffic is expected to divert to the expanded Alaskan Way along the
36 waterfront to avoid the congestion in the tunnel and north of the tunnel as
37 a result of the BAT lane conversion.

- 1 • Travel speeds for the 2015 Partial Program and 2030 Program confirm the
2 LOS findings. Projected speeds are similar to those in the 2015 and 2030
3 Project, with the exception of slightly higher southbound speeds and
4 substantially lower northbound speeds in the northern part of the project
5 area.
- 6 • In the southbound direction, speeds are expected to decline somewhat
7 (e.g., from 32 mph to 28 mph in the AM peak hour) between the north
8 tunnel portal and the Aurora Bridge in the 2030 Program as compared to
9 the Project. This is due to the constraint caused by the conversion of a
10 general purpose lane to a BAT lane in this section. The more substantial
11 effect of the constrained section of SR 99, however, is expected to be
12 reflected on southbound SR 99 north of the beginning of the BAT lanes.
13 The analyses indicate that southbound AM peak hour speeds would
14 decrease to less than 20 mph across the Aurora Bridge as a result of the
15 BAT lane conversion.

16 Alaskan Way Viaduct Mainline and Ramp Volumes

17 This section describes the AM peak hour, PM peak hour, and daily traffic volume
18 estimates for the 2015 Partial Program and 2030 Program scenarios. Anticipated
19 changes from the 2015 Project and 2030 Project are discussed in detail below.

20 AM Peak Hour

21 Exhibits 7-9 and 7-10 show the volumes in the AM peak hour for the 2015 Partial
22 Program and the 2030 Program scenarios, respectively.

23 2015 Partial Program

24 The 2015 Partial Program volume estimates are generally similar to the 2015 Project
25 forecasts, with modest increases in volumes for most mainline and ramp segments
26 south of downtown, modest decreases in the bored tunnel, and increases north of
27 downtown. Vehicle volumes in the bored tunnel are expected to decrease slightly to
28 approximately 2,900 vehicles southbound and 3,500 northbound. These decreases
29 are due to the new connection provided between Elliott and Western Avenues and
30 Alaskan Way on the central waterfront. With the connection in place, some vehicles
31 that would otherwise use the bored tunnel would now use the connection to the
32 central waterfront. AM peak hour mainline ramp volumes forecasted for the 2015
33 Partial Program are shown in Exhibit 7-9.

34 2030 Program

35 As with the 2015 Partial Program, the 2030 Program volume estimates are generally
36 similar to the 2030 Project forecasts, with modest increases in volumes for most
37 mainline and ramp segments south of downtown and modest decreases in the bored

1 tunnel and ramps in the South Lake Union area. The one exception is a substantial
2 decrease in both directions on the SR 99 mainline north of downtown with the 2030
3 Program. This is due to the conversion of one lane in each direction to a BAT lane,
4 which substantially decreases the capacity of the mainline. Vehicle volumes in the
5 bored tunnel are expected to decrease slightly to approximately 2,900 vehicles
6 southbound and 3,500 northbound. As with the 2015 Partial Program, these
7 decreases are due to the new connection between Elliott and Western Avenues and
8 Alaskan Way, as well as the capacity constraint on SR 99 north of the tunnel caused
9 by the BAT lane conversion. AM peak hour mainline ramp volumes forecasted for
10 the 2030 Program are shown in Exhibit 7-10.

11 PM Peak Hour

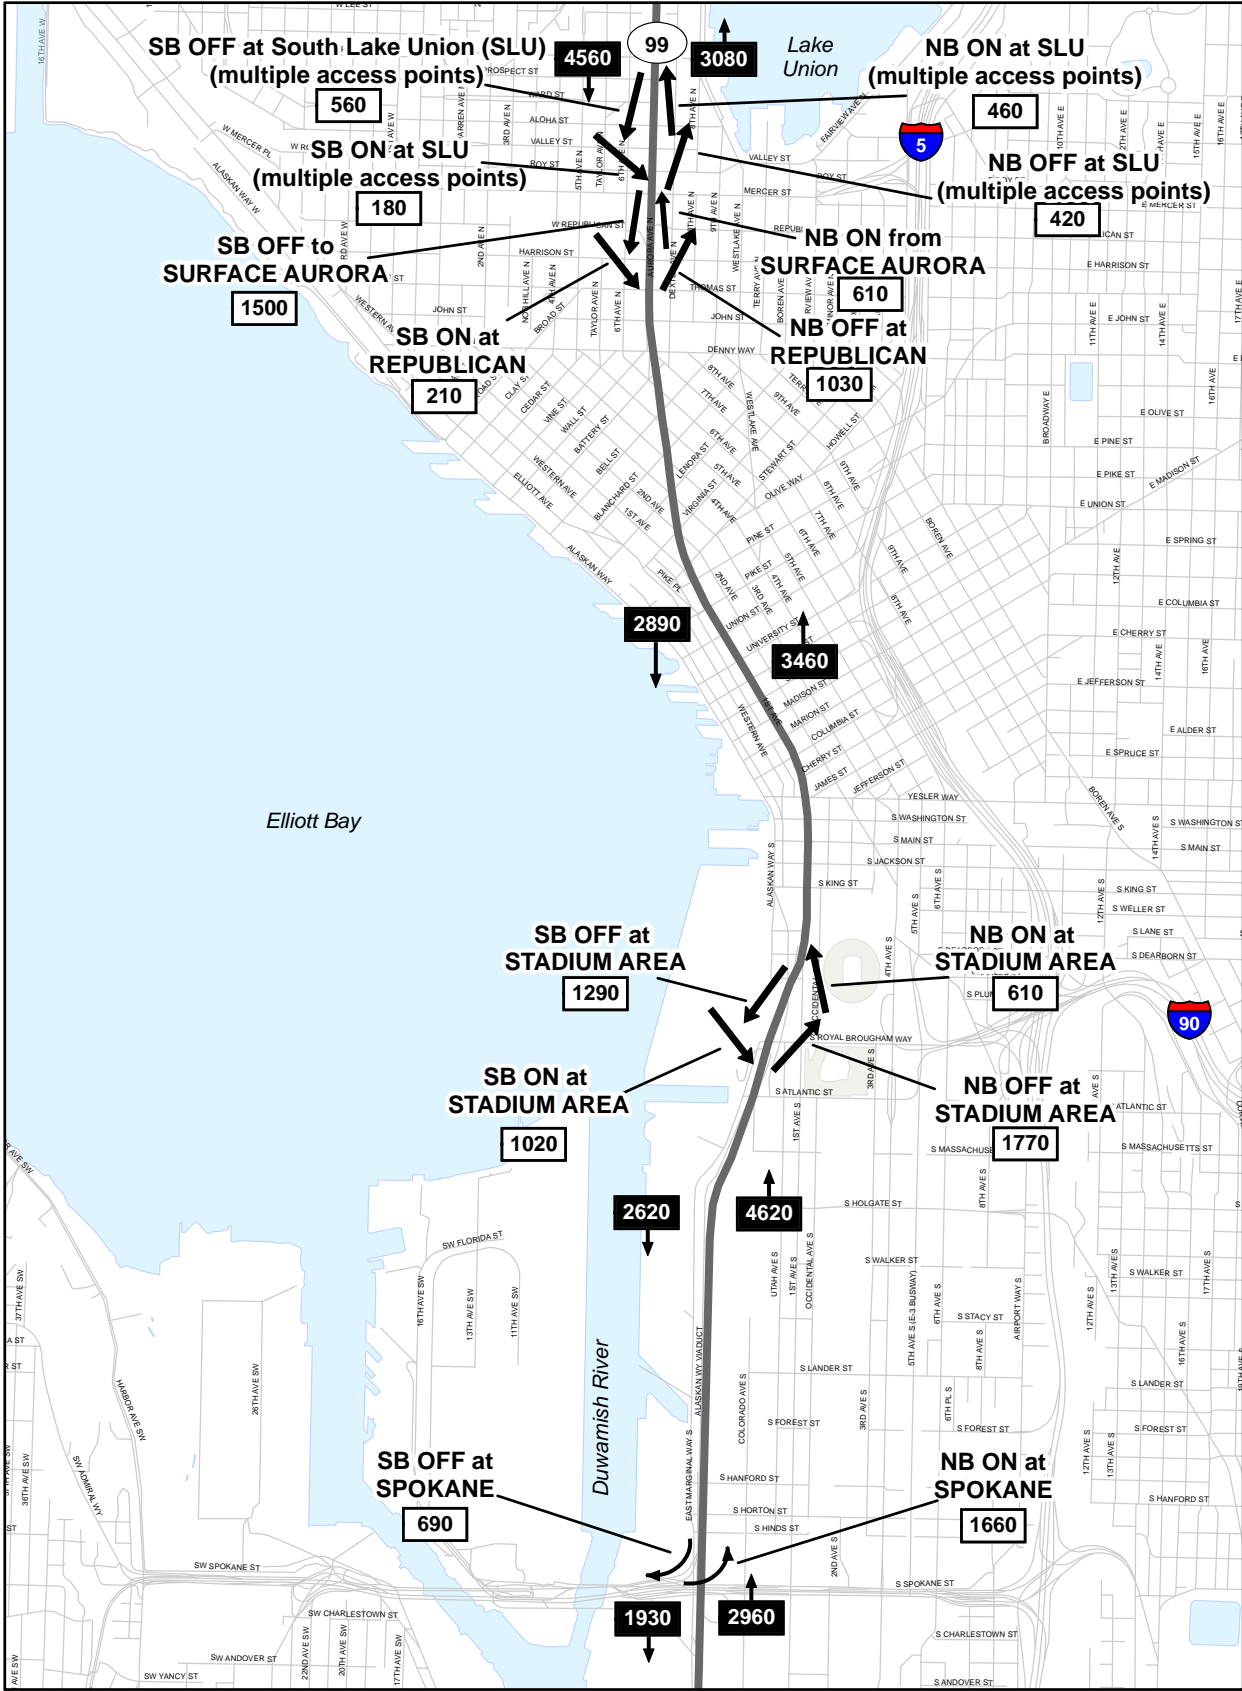

12 Exhibits 7-11 and 7-12 show the volumes in the PM peak hour for the 2015 Partial
13 Program and the 2030 Program scenarios, respectively.

14 2015 Partial Program

15 As in the AM peak hour, the 2015 Partial Program volume estimates are generally
16 similar to the 2015 Project forecasts, with modest increases in volumes for most
17 mainline and ramp segments south of downtown, modest decreases in the bored
18 tunnel, and increases north of downtown. Vehicle volumes in the bored tunnel are
19 expected to decrease slightly to approximately 3,300 vehicles southbound and 3,900
20 northbound. These decreases are due to the new connection provided between
21 Elliott and Western Avenues and Alaskan Way on the central waterfront. With the
22 connection in place, some vehicles that would otherwise use the bored tunnel would
23 now use the connection to the central waterfront. PM peak hour mainline ramp
24 volumes forecasted for the 2015 Partial Program are shown in Exhibit 7-11.

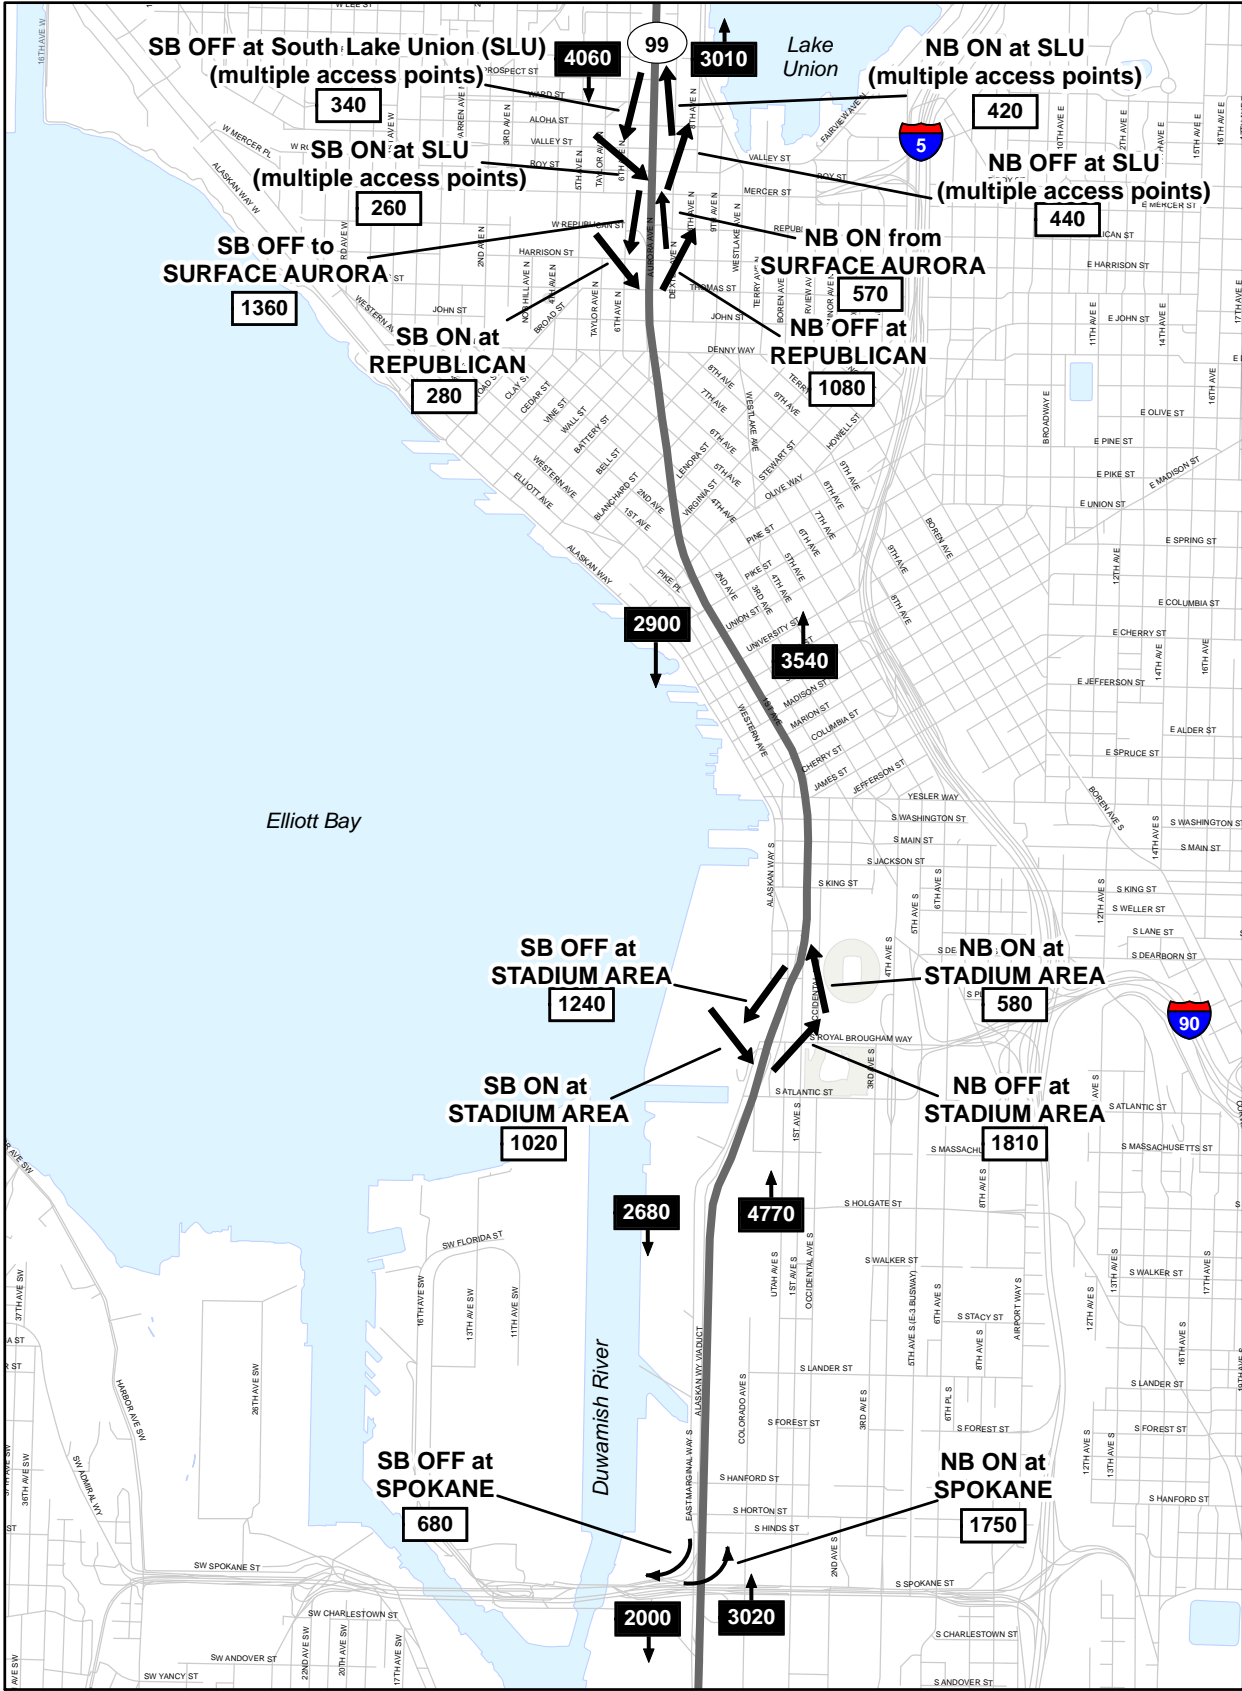

25 2030 Program

26 As with the 2015 Partial Program, the 2030 Program volume estimates are generally
27 similar to the 2030 Project forecasts, with modest increases in volumes for most
28 mainline and ramp segments south of downtown and modest decreases in the bored
29 tunnel and ramps in the South Lake Union area. As in the AM peak hour, the one
30 exception is a substantial decrease in both directions on the SR 99 mainline north of
31 downtown with the 2030 Program. This is again due to the conversion of one lane in
32 each direction to a BAT lane, which substantially decreases the capacity of the
33 mainline. Vehicle volumes in the bored tunnel are expected to decrease slightly to
34 approximately 3,400 vehicles southbound and 4,000 northbound. As with the 2015
35 Partial Program, these decreases are due to the new connection between Elliott and
36 Western Avenues and Alaskan Way, as well as the capacity constraint on SR 99
37 north of the tunnel caused by the BAT lane conversion. PM peak hour mainline
38 ramp volumes forecasted for the 2030 Program are shown in Exhibit 7-12.

 2030 Program**

1 Daily

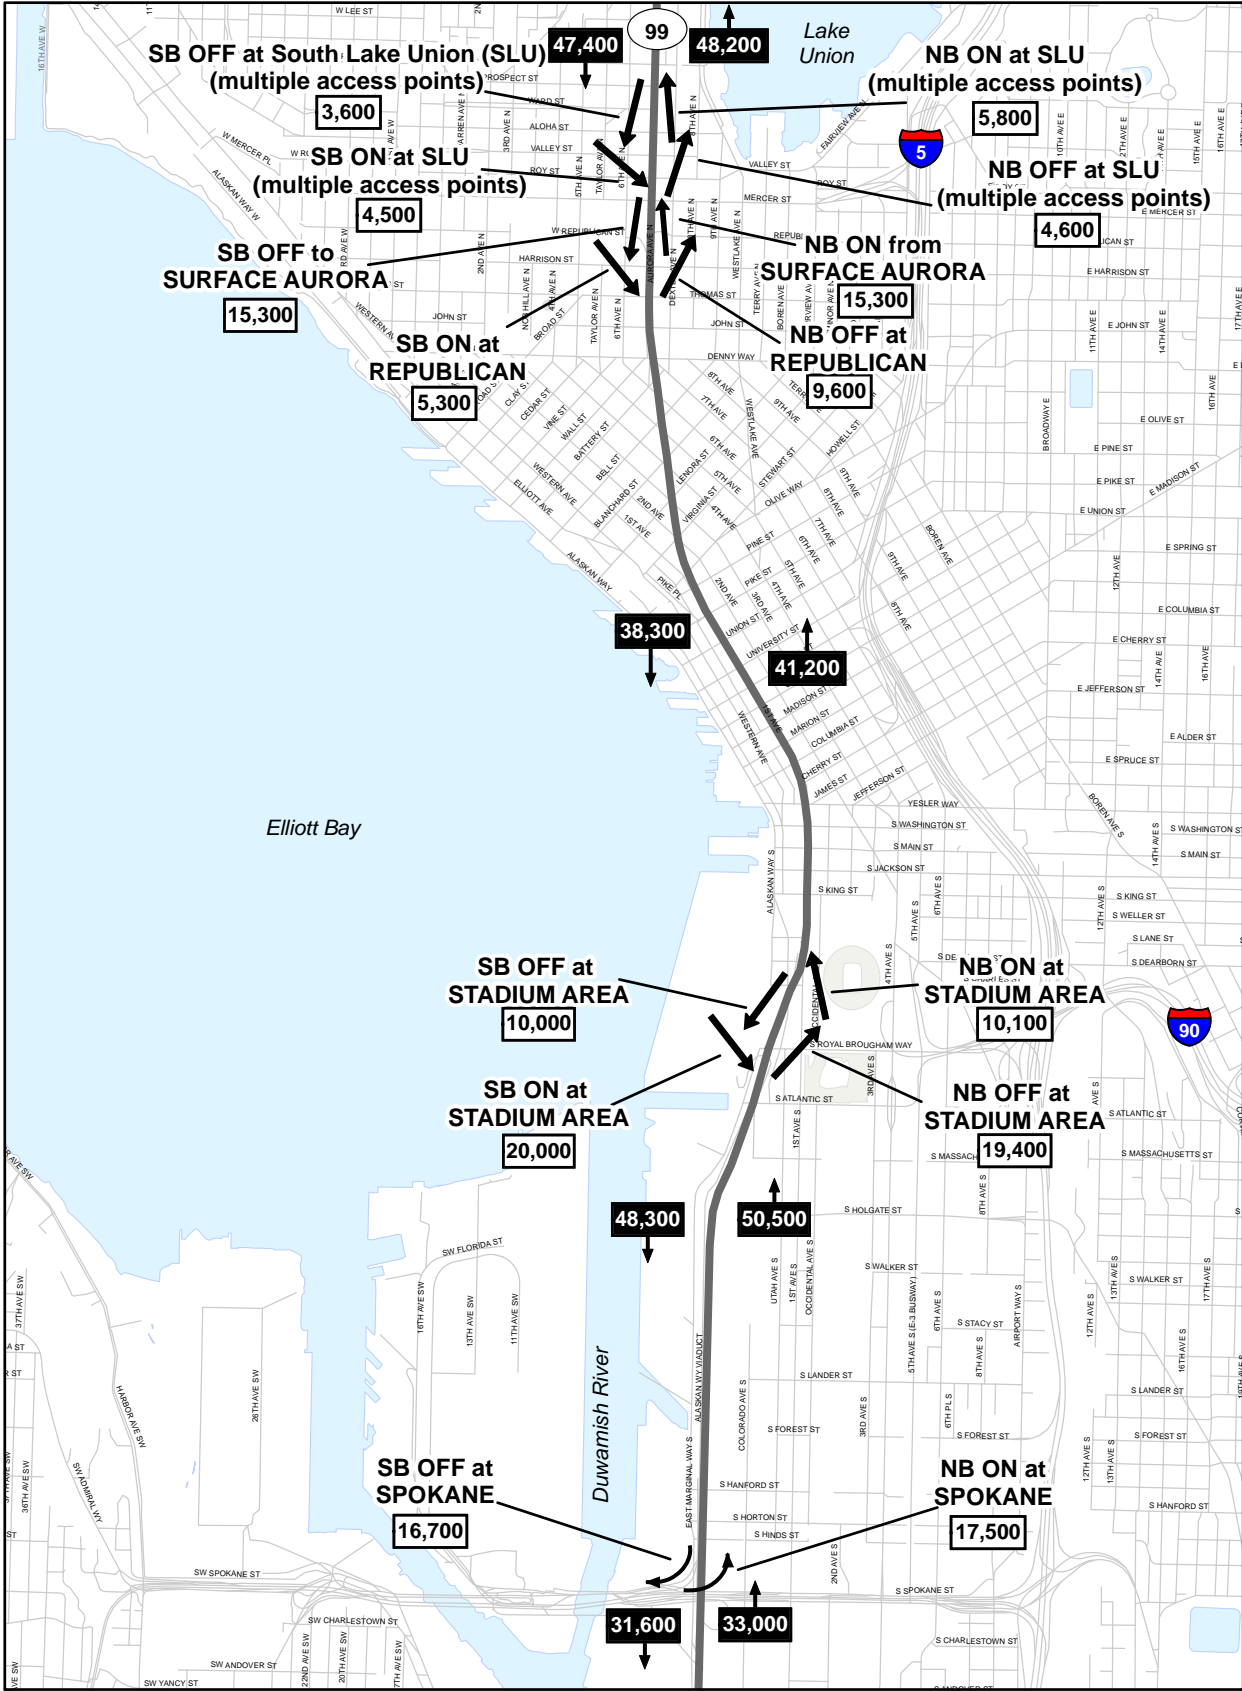

2 Exhibits 7-13 and 7-14 show the daily volumes for the 2015 Partial Program and
3 the 2030 Program scenarios, respectively.

4 2015 Partial Program

5 As in the AM and PM peak hours, the 2015 Partial Program volume estimates are
6 generally similar to the 2015 Project forecasts, with modest increases in volumes for
7 most mainline and ramp segments south of downtown, modest decreases in the
8 bored tunnel, and increases north of downtown. Vehicle volumes in the bored
9 tunnel are expected to decrease slightly to approximately 38,300 vehicles
10 southbound and 41,200 northbound. These decreases are due to the new connection
11 provided between Elliott and Western Avenues and Alaskan Way on the central
12 waterfront. With the connection in place, some vehicles that would otherwise use
13 the bored tunnel would now use the connection to the central waterfront. Daily
14 mainline ramp volumes forecasted for the 2015 Partial Program are shown in Exhibit
15 7-13.

16 2030 Program

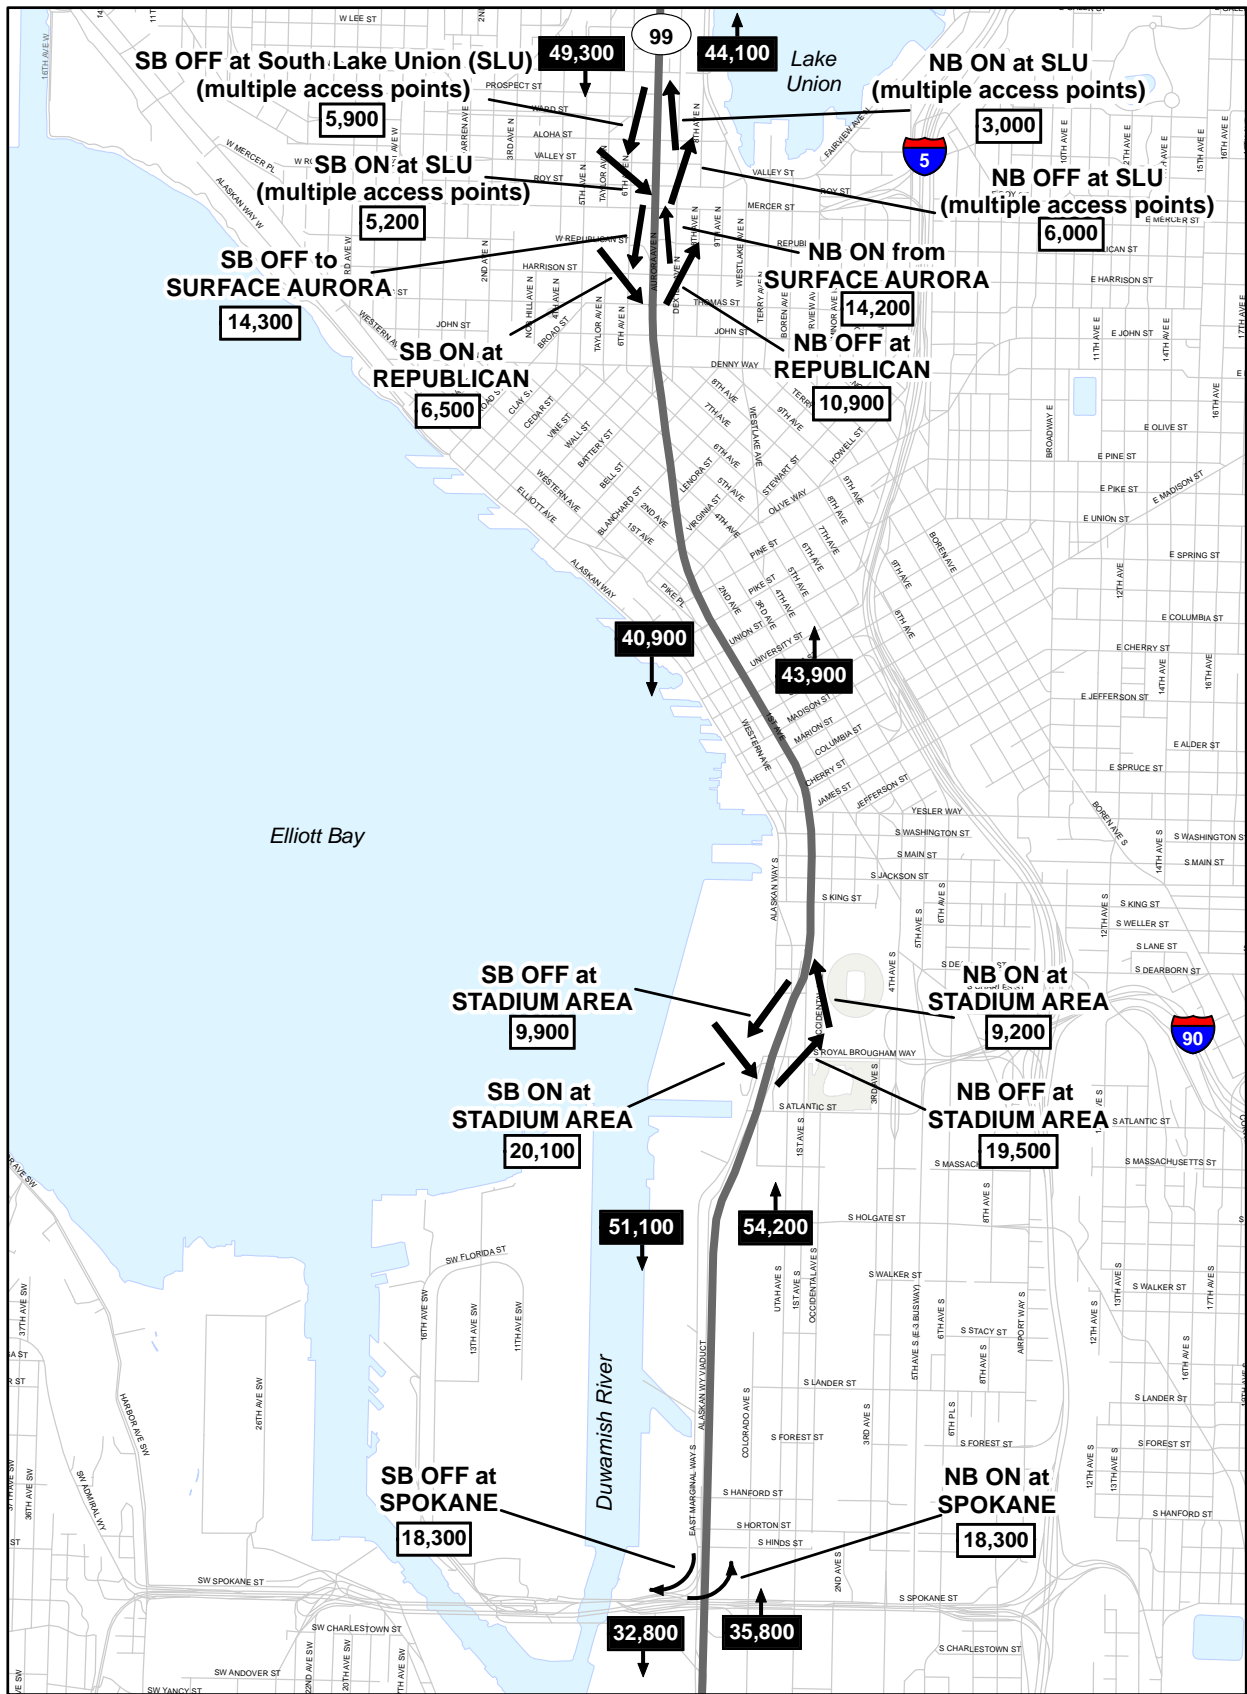

17 As with the 2015 Partial Program, the 2030 Program volume estimates are
18 generally similar to the 2030 Project forecasts, with modest increases in volumes
19 for most mainline and ramp segments south of downtown and modest decreases
20 in the bored tunnel and ramps in the South Lake Union area. As in the AM and
21 PM peak hours, the one exception is a substantial decrease in both directions
22 on the SR 99 mainline north of downtown with 2030 Program. This is again due to
23 the conversion of one lane in each direction to a BAT lane, which substantially
24 decreases the capacity of the mainline. Vehicle volumes in the bored tunnel are
25 expected to decrease slightly to approximately 41,000 vehicles southbound and
26 44,000 northbound. As with the 2015 Partial Program, these decreases are due to
27 the new connection between Elliott and Western Avenues and Alaskan Way, as
28 well as the capacity constraint on SR 99 north of the tunnel caused by the BAT
29 lane conversion. Daily mainline ramp volumes forecasted for the 2030 Program
30 are shown in Exhibit 7-14.

1 **SR 99 Mainline Level of Service**

2 This section describes the AM and PM peak hour LOS for corridor segments
 3 under the 2015 Project, 2015 Partial Program, 2030 Project, and 2030 Program
 4 scenarios. While LOS provides a general gauge of how a facility performs overall,
 5 it is not considered a comprehensive measure for comparing scenarios for
 6 mainline conditions because ramp locations and segment arrangements may vary
 7 considerably among the scenarios. Additionally, as indicated in Chapter 2,
 8 because SR 99's posted speeds are less than the speeds on a typical freeway, the
 9 LOS as based on the HCM density ranges for freeways would likely be lower than
 10 the actual speeds on the facility. Hence, the mainline LOS results are better suited
 11 for a relative comparison between scenarios as opposed to a true indication of
 12 operating performance. Projected speeds and travel times along the facility is a
 13 better indicator of expected performance. The SR 99 mainline LOS is summarized
 14 by segment for the 2015 Project, 2015 Partial Program, 2030 Project, and 2030
 15 Program scenarios in Exhibits 7-15 to 7-18, reflecting both directions in the AM
 16 and PM peak hours.

4

5 2015 Partial Program Level of Service

6 With implementation of the 2015 Partial Program, the mainline LOS is expected to
 7 be similar to that projected for the 2015 Project. The bored tunnel segment of the
 8 mainline is projected to operate at LOS D in the southbound direction during
 9 both the AM and PM peak hours, similar to the 2015 Project. Similarly,
 10 northbound operations are projected to remain at LOS E during both the AM and
 11 PM peak hours.

12 In the south end of the project area from approximately S. Spokane Street to the
 13 stadium off-ramp area, northbound SR 99 speeds and densities would remain at
 14 LOS D levels during both the AM and PM peak hours. Mainline performance in
 15 the southbound direction would remain at LOS C in the AM peak hour and at
 16 LOS D in the PM peak hour.

17 In the north end of the project area, southbound conditions are expected to
 18 remain at LOS E during both the AM and PM peak hours. Northbound
 19 conditions would remain at LOS D in the AM peak hour and at LOS F in the PM
 20 peak hour.

1 **2030 Program Level of Service**

2 Similar to 2015 Partial Program, implementation of the 2030 Program is generally
3 projected to result in similar mainline traffic operations as those with the 2030
4 Project, with some improvement in LOS in the south end of the project area and
5 some decline in LOS in the north end of the project area.

6 The bored tunnel segment of the mainline is projected to remain at LOS D in the
7 southbound direction during the AM peak hour and at LOS E in the PM peak
8 hour. Northbound operations are projected to remain at LOS E during the AM
9 peak hour and at LOS F during the PM peak hour.

10 In the south end of the project area from approximately S. Spokane Street to the
11 stadium area off-ramp, northbound SR 99 speeds and densities would remain at
12 LOS E levels during the AM peak hour. However, during the PM peak hour,
13 northbound mainline operations are projected to improve from LOS F to LOS E
14 with the 2030 Program. This improvement is due to a higher number of vehicles
15 leaving the mainline and a lower number of vehicles entering the mainline in the
16 stadium area. This reduction in vehicles using SR 99 north of the stadium area is
17 anticipated to occur as a result of increased capacity on Alaskan Way along the
18 waterfront, as well as congestion on SR 99 north of downtown due to reduced
19 capacity on the mainline with the addition of the BAT lanes. Mainline
20 performance in the southbound direction would improve from LOS C to LOS B in
21 the AM peak hour. This improvement is anticipated to occur due to congested
22 operations in the north end of the project area, which would result in a bottleneck
23 condition in which fewer vehicles are able to get through the project area.
24 Southbound operations would remain at LOS D in the PM peak hour.

25 In the north end of the project area, southbound conditions are expected to
26 remain at LOS F during the AM peak hour and at LOS E during the PM peak
27 hour. Northbound conditions would remain at LOS D in the AM peak hour. In
28 the PM peak hour, northbound operations would decline from LOS E to LOS F.
29 Again, this degraded LOS is anticipated to occur as a result of reduced capacity
30 on the mainline with the addition of the BAT lanes north of the project area.

31 **SR 99 Mainline Speeds**

32 This section discusses the AM and PM peak hour travel speeds for corridor
33 segments under the 2015 Project, 2015 Partial Program, 2030 Project, and 2030
34 Program scenarios. As with LOS, comparing travel speeds between scenarios can
35 present certain challenges because the ramp and segment arrangements vary
36 among the scenarios. To assist in this comparison, the results are presented side
37 by side graphically in Exhibits 7-19 and 7-20. The speeds are also presented in
38 tabular format in Exhibits 7-21 to 7-24.

1 Segment travel speed results for the 2015 Partial Program and 2030 Program
2 confirm the LOS findings, with speeds on most segments projected to be similar
3 to those projected for the 2015 Project and 2030 Project. Southbound speeds in the
4 bored tunnel are expected to remain at approximately 45 to 46 mph in both the
5 AM and PM peak hours in both the 2015 Partial Program and the 2030 Program.
6 In the northbound direction, speeds in the tunnel are expected to remain at
7 approximately 43 to 44 mph in the AM peak hour in both the 2015 Partial
8 Program and the 2030 Program. However, in the PM peak hour, while speeds are
9 expected to be similar between the 2015 Project and Partial Program, the reduced
10 mainline capacity due to the BAT lanes north of downtown is anticipated to result
11 in substantially slower speeds with the 2030 Program (approximately 20 mph
12 compared with 40 mph with the 2030 Project).

13 In the south end of the project area from S. Spokane Street to the stadium off-
14 ramp area, speeds on SR 99 in both directions with the 2015 Partial Program are
15 expected to be similar to the 2015 Project conditions in the AM and PM peak
16 hours. With the 2030 Program, speeds during the AM peak hour are projected to
17 increase in both directions compared with the 2030 Project, increasing from 45 to
18 48 mph in the southbound direction and from 40 to 44 mph in the northbound
19 direction. As described previously with LOS, these increases are expected to
20 occur as a result of more northbound vehicles using alternate routes such as
21 Alaskan Way on the waterfront and fewer southbound vehicles being allowed to
22 travel through the project area due to congestion north of downtown. During the
23 PM peak hour, travel speeds are expected to remain similar to the 2030 Project in
24 the southbound direction and to increase from 32 to 34 mph in the northbound
25 direction.

26 In the north end of the project area, southbound speeds during the AM peak hour
27 with the 2015 Partial Program are expected to be slower, at 29 mph, compared to
28 33 mph in the 2015 Project scenario. Northbound speeds would be similar to
29 those in the Project scenario. In the PM peak hour, southbound speeds would be
30 similar between the Project and Partial Program, but northbound speeds would
31 decline from 35 to 33 mph. Speeds for the north end in the 2030 Program scenario
32 are anticipated to follow a similar trend as that seen with the 2015 Partial
33 Program, with an even more substantial reduction in speeds in the northbound
34 direction during the PM peak hour (declining from 35 mph with the 2030 Project
35 to 19 mph with the 2030 Program). Again, this reduction in speeds is mainly due
36 to the reduced capacity on the SR 99 mainline with the addition of the BAT lanes
37 north of downtown. Speeds in the southbound direction during the AM peak
38 hour are expected to decline from 32 mph with the 2030 Project to 28 mph with
39 the 2030 Program. Note that the true effect of the constrained section of SR 99 is
40 expected to be reflected on southbound SR 99 north of the beginning of the BAT

lanes. Analyses indicate that southbound AM peak hour speeds would slow to less than 20 mph across the Aurora Bridge as a result of the BAT lane conversion.

7.1.3 Traffic Operations at Key Arterial Intersections

Key Findings

- Average intersection delays and LOS for the 2015 Partial Program and 2030 Program scenarios would generally be similar to Project conditions.
- In the south end, no substantial changes are anticipated for the Partial Program or Program aside from enhanced transit service for the 2030 Program. As such, intersection operations would likely be similar to the Project scenarios.
- In the central sub-area, the Elliott/Western Connector to/from the Alaskan Way surface street is expected to draw greater north-south peak hour demands to the waterfront area. Intersection congestion could therefore increase slightly for higher volume locations on Alaskan Way.
- In the north end, the changes to Mercer Street (extension to Elliott Avenue) would not substantially affect intersection delays for the 2015 Partial Program or 2030 Program compared to Project conditions. However, the Elliott/Western Connector may slightly draw traffic away from the Mercer Street corridor and the SR 99 corridor, potentially reducing intersection delays at locations near or west of the mainline.
- Intersection operations in 2030 Program conditions are expected to remain similar to 2030 Project conditions.

South Sub-Area

Detailed results of the intersection analysis for the south sub-area are not provided in this section. However, a qualitative discussion of potential congestion hot spots and general comparisons to Project conditions is provided. Intersection performance for a selected number of study locations was evaluated using Synchro and VISSIM traffic analysis software.

2015 Partial Program

Under the 2015 Partial Program scenario, traffic patterns in the south end of the project area would be similar to the 2015 Project scenario and would reflect the relocation of the SR 99 stadium ramps and the introduction of newly created intersections in the network within the study area. With no network differences between the Project and Partial Program scenarios, similar congestion hot spots would likely arise during the PM peak hour. These intersections include First Avenue S. at S. Atlantic Street, S. Royal Brougham Way at Fourth Avenue S. and First Avenue S. at Yesler Way. Delays at each of these locations would likely

1 reflect LOS E conditions or worse. Congestion levels for the AM peak hour
2 would be modest by comparison, with all intersections in the south end likely
3 operating at LOS D or better.

4 2030 Program

5 For the 2030 Program scenario, the street network in the south end of the project
6 area would be similar to the 2015 Partial Program and 2030 Project scenarios,
7 which again includes the full range of planned improvements included in the
8 Baseline scenario (S. Holgate Street to S. King Street Viaduct Replacement Project
9 and SR 519 Intermodal Access Project – Phase 2) as well as the replacement of the
10 stadium area ramps and the introduction of several new intersections along the
11 East Frontage Road. Also included as part of the 2030 Program package are
12 transit service enhancements and increases across the King Country Metro bus
13 system.

14 With little to no change in the street network between 2030 Project and 2030
15 Program conditions but with the proposed transit service enhancements
16 incorporated, delays and LOS under the 2030 Program are expected to be similar
17 to 2030 Project conditions, if not slightly improved.

18 Specific AM peak hour hot spots identified for the 2030 Project scenario that
19 would operate at high levels of congestion under 2030 Program conditions
20 include the E. Marginal Way (Terminal 46 Driveway)/S. Atlantic Street, First
21 Avenue S./S. Atlantic Street, First Avenue S./S. Dearborn Street, and Fourth
22 Avenue S./S. Royal Brougham Way. For PM peak hour conditions, the
23 intersections of First Avenue S. at S. Atlantic Street and Fourth Avenue S. at
24 S. Royal Brougham Way would also likely operate at LOS E or LOS F.

25 **Central Sub-Area**

26 As with the south end, no specific technical results or tables are provided in this
27 discussion of intersection operations in the central sub-area. However,
28 congestion levels at intersections in 2030 Program are qualitatively compared to
29 those described in the 2030 Project discussion to highlight the similarities between
30 the scenarios.

31 2015 Partial Program

32 Under the 2015 Partial Program scenario, removal of the downtown SR 99 on- and
33 off-ramps would be identical to the network changes described for the 2015
34 Project. As previously discussed, the affected ramps would include the Columbia
35 Street southbound on-ramp, the Seneca Street northbound off-ramp, the Western
36 Avenue northbound off- and on-ramps, the Battery Street off-ramp, and the
37 Elliott Avenue on-ramp. Traffic would use the south end stadium area ramps or

1 the north end interchange and take surface streets into downtown. The only
2 congestion hot spot previously identified for 2015 Project conditions that would
3 apply to the 2015 Partial Program scenario is the intersection of Western Avenue
4 at Broad Street.

5 A new connector would be introduced in the 2015 Partial Program (versus the
6 2015 Project) that would provide direct access from Elliott Avenue and Western
7 Avenue to/from the Alaskan Way surface street. This connector is expected to
8 draw additional traffic to Alaskan Way and Elliott/Western compared to 2015
9 Project conditions. Congestion levels on Elliott Avenue and Western Avenue
10 near Broad Street and at key intersections along the waterfront such as Alaskan
11 Way at Madison Street and Alaskan Way at Columbia Street may increase as a
12 result of the higher traffic volumes.

13 Some marginal reductions in delay may occur at some intersections in the central
14 sub-area due to enhanced transit service and potential reductions in overall
15 vehicular demand. However, such a mode shift to transit between the Project and
16 Program scenarios is not expected to affect overall intersection delays to a degree
17 sufficient enough to influence peak hour LOS.

18 2030 Program

19 Under 2030 Program conditions, the majority of intersections are anticipated to
20 operate similarly to 2030 Project conditions in the central sub-area. During the
21 AM peak hour, the only critical hot spot identified previously for the 2030 Project
22 scenario was Second Avenue at Marion Street. Similar delays could be expected
23 at this location for 2030 Program conditions. For the PM peak hour, the
24 intersection of Western Avenue at Broad Street is anticipated to operate at the
25 high levels of congestion for the 2030 Project scenario and would experience
26 similar congestion under 2030 Program conditions.

27 As discussed for the 2015 Partial Program, additional intersections that may
28 experience high levels of congestion under 2030 Program conditions could
29 include intersections along Elliott Avenue and Western Avenue near Broad Street
30 due to the new connection between the Alaskan Way surface street to/from Elliott
31 Avenue and Western Avenue. Higher demands on Alaskan Way due to this new
32 connection may increase congestion levels at key intersections along the
33 waterfront such as Alaskan Way at Madison Street and Alaskan Way at Columbia
34 Street.

35 The enhancements in transit service expected as part of the 2030 Program scenario
36 elements may help to reduce general purpose vehicle demands on city streets and
37 consequently result in an overall decrease in intersection delays. These effects
38 may be more pronounced for the 2030 horizon compared to 2015 conditions due

1 to higher overall traffic volumes and congestion levels, which may lead to greater
2 potential for mode shift.

3 North Sub-Area

4 As discussed in Chapter 5, two configurations for Sixth Avenue N. and the
5 southbound on-ramp are being considered in the north end, reflecting how Sixth
6 Avenue N. is aligned between approximately Republican Street and Mercer
7 Street. Detailed results of the intersection analysis for the north sub-area are not
8 provided in this section; instead a qualitative discussion is provided to draw
9 comparisons and note similarities between the Project and Program conditions for
10 the 2015 and 2030 horizons.

11 2015 Partial Program

12 For the 2015 Partial Program scenario, network changes in the north end would
13 be similar to those described for 2015 Project conditions. East-west arterials such
14 as John, Thomas, and Harrison Streets would all intersect with a new north-south
15 arterial (surface Aurora Avenue) with east-west through movements allowed,
16 and the northbound SR 99 off-ramp south of Mercer Street and the southbound
17 on-ramp would both be located at Republican Street. Additional surface street
18 changes would include the closure of Broad Street, extending Sixth Avenue to
19 Mercer Street, and the conversion of Sixth Avenue N. from one-way to two-way
20 between Denny Way and Battery Street. The only major difference between the
21 Project and Partial Program elements is the extension of two-way Mercer Street
22 from Fifth Avenue N. to Elliott Avenue under the Partial Program.

23 The extension of Mercer Street as a two-way arterial (to Elliott Avenue) is not
24 expected to affect traffic distributions or congestion levels substantially in the
25 Uptown neighborhood. For the AM peak hour, similar intersection delays would
26 be expected for the 2015 Partial Program compared to 2015 Project conditions.
27 Key congestion hot spots identified previously under the Project scenario include
28 Valley Street at Fairview Avenue N., Mercer Place at Elliott Avenue, Dexter
29 Avenue at Mercer Street, and Fairview Avenue at Mercer Street. These
30 intersections are expected to operate at LOS E or worse during the AM peak hour.

31 Similar to Project conditions, the intersections of Mercer Street at Fairview
32 Avenue N., Mercer Street at Westlake Avenue N., and Mercer Place at Elliott
33 Avenue are expected to experience long delays and pronounced queuing during
34 the PM peak hour. Also, the intersection of Sixth Avenue and Battery Street is
35 anticipated to experience long delays for the 2015 Partial Program.

36 Option 2 in the north end would include a modified Sixth Avenue N. alignment
37 near Republican Street and the on-ramp to southbound SR 99. As described
38 previously in Chapter 5, this option would align Sixth Avenue farther to the east

1 between Republican Street and Mercer Street and restrict movements at the
2 resulting intersection with Mercer Street. No westbound or northbound left turns
3 would be allowed at the new intersection on Mercer Street. For the 2015 Partial
4 Program scenario, intersection delays for affected intersections under Option 2
5 would not be expected to change noticeably from those for the original concept
6 for Sixth Avenue N. despite some rerouting of trips accessing the southbound on-
7 ramp to SR 99 at Republican Street.

8 The Elliott/Western Connector may draw some traffic volumes away from SR 99
9 into and out of the South Lake Union and Uptown neighborhoods due to a more
10 direct north-south route along the central waterfront. Trips originating from or
11 destined to the Interbay and Ballard areas that may have used the SR 99 bored
12 tunnel may shift to Elliott and Western Avenues, thereby reducing demands on
13 east-west arterials such as Mercer Street. As a result, congestion levels at
14 intersections in the north end may be slightly lower for locations near and/or west
15 of the SR 99 corridor.

16 2030 Program

17 Under the 2030 Program scenario, most intersections in the north end are
18 expected to operate at levels similar to 2030 Project conditions. During the AM
19 peak hour, similar intersections are anticipated to operate under congested
20 conditions as those expected to be congested in the 2030 Project scenario, which
21 includes key hot spots such as Mercer Street at Dexter Avenue, Valley Street at
22 Fairview Avenue, and the gateway intersection of Mercer Street at Fairview
23 Avenue/I-5 ramps. Other locations would also operate at LOS E or worse for the
24 2030 Program as highlighted in the 2030 Project discussion.

25 During the PM peak hour for the 2030 Program scenario, similar hot spots as
26 those described above for AM peak hour conditions would occur. However,
27 additional locations such as Denny Way at Aurora Avenue, Dexter Avenue at
28 Denny Way, Ninth Avenue at Mercer Street, and Denny Way at Aurora
29 Avenue/Battery Street/Wall Street would also be included on the list of highly
30 congested intersections during the PM peak hour.

31 Two scenario elements that may result in slightly lower congestion levels for the
32 2030 Program scenario compared to the 2030 Project include the Elliott/Western
33 Connector and the enhanced transit service levels. The Elliott/Western Connector
34 may potentially draw some traffic volumes away from SR 99 into and out of the
35 South Lake Union and Uptown neighborhoods due to a more direct routing of
36 trips along the central waterfront, while increased transit service may capture
37 some mode shift in the north end. Congestion levels at intersections in the north
38 end may be slightly lower for locations near and/or west of the SR 99 corridor as
39 result.

1 As discussed in the mainline operations section for the 2030 Program, northbound
2 and southbound SR 99 from Aloha Street to the north may include a right-side
3 transit-only lane that would essentially convert a general purpose lane into a
4 designated bus lane. Preliminary analyses of operations including these bus lanes
5 have shown high levels of mainline congestion that is likely to constrain inbound
6 and outbound capacity on SR 99. The details of such constraints on intersection
7 operations are unknown. However, in the southbound direction (particularly for
8 the AM peak hour), this may translate to fewer trips entering the system and
9 lower congestion levels at the north end intersections. For the northbound
10 direction, the mainline constraint could result in spillback of northbound ramp
11 traffic to local streets and longer delays overall during the PM peak hour.

12 7.1.4 Peak Hour Travel Times

13 Key Findings

- 14 • Travel times for the specific paths and time periods examined are not
15 expected to change substantially from 2015 Project to 2015 Partial Program
16 conditions. Similar consistency could be expected for the comparison of
17 selected 2030 Project and 2030 Program travel times. Only the Ballard to
18 Spokane Street route is discussed for the 2030 scenarios.
- 19 • While nearly all differences in travel time between the 2015 Project and the
20 2015 Partial Program are within 5 to 7 percent, the northbound route from
21 Spokane Street to Ballard via SR 99, the Alaskan Way surface street, and
22 Elliott Avenue/15th Avenue N.W. would take 6 minutes less under 2015
23 Partial Program conditions compared to 2015 Project conditions (PM peak
24 hour). This 20 percent reduction in travel time is likely attributed to the
25 new Elliott/Western Connector that is introduced to provide more direct
26 access between the waterfront (Alaskan Way) and the Elliott Avenue and
27 Western Avenue one-way couplet.
- 28 • Differences in travel times from Ballard to Spokane Street for the 2030
29 Project and 2030 Program scenarios are similar to those highlighted for the
30 2015 scenarios, although less pronounced in magnitude. For the AM peak
31 hour, travel times are generally similar (within 2 to 4 percent) in both
32 directions. For PM peak hour conditions, the northbound travel time for
33 the 2030 Program is reduced by 2.5 minutes compared to 2030 Project
34 conditions. This represents an 8 percent reduction from the 2030 Project to
35 the 2030 Program and is again attributed to the new connector for Elliott
36 Avenue and Western Avenue to/from Alaskan Way.

37 Peak hour travel times for the Project and Program scenarios are shown in Exhibit
38 7-25.

1 Exhibit 7-25. Corridor Travel Times for the Project, Partial Program, and Program

3 Estimated travel times shown in minutes.

4 West Seattle to CBD

5 As described in Chapter 5, this route extends from the intersection of California
 6 Avenue and Alaska Junction to the CBD (Fourth Avenue and Seneca Street) and
 7 is presented for the peak direction trip only (i.e., inbound in the AM and
 8 outbound in the PM peak period).

9 Travel times for this route would be similar between the 2015 Project and 2015
 10 Partial Program. Travel times differences are generally no greater than 1 to
 11 2 minutes (less than 5 to 7 percent) for either direction or time period.

1 **Woodland Park to CBD**

2 This route is defined by the SR 99 corridor from N. 50th Street to downtown
3 Seattle and is described for the peak direction trip only. Travel times for the 2015
4 Project and 2015 Partial Program scenarios are generally similar for either the AM
5 or PM peak hour and for both directions.

6 **Woodland Park to S. Spokane Street**

7 Changes to the larger roadway network as part of the 2015 Partial Program,
8 which include the Elliott/Western Connector and the extension of two-way
9 Mercer Street to Fifth Avenue N., would not affect travel times for this route. As
10 a result, travel times for both directions and time periods are expected to be
11 within 0.5 minute for the 2015 Project and the 2015 Partial Program.

12 **Ballard Bridge to Spokane Street (via Alaskan Way Viaduct and/or Alaskan Way)**

13 This route is defined by a north end point of Ballard and a south end point near
14 the Duwamish area at Spokane Street and is the only travel time route for which
15 comparisons between the 2015 and 2030 scenarios are provided.

16 The main network change influencing travel times along this route is the
17 introduction of the Elliott/Western Connector in the 2015 Partial Program and
18 2030 Program. This connector would provide more direct access between the
19 Alaskan Way surface street and the Elliott/Western one-way couplet and would
20 allow north-south traffic to avoid the railroad conflicts in the north end of
21 Alaskan Way near Elliott Avenue at Broad Street.

22 Based on the analysis findings, travel times under AM peak hour conditions are
23 generally similar between the 2015 Project and the 2015 Partial Program and
24 between the 2030 Project and the 2030 Program, are generally similar. However,
25 for the PM peak hour, the high concentrations of traffic through the central
26 waterfront and to Ballard/Interbay (northbound) would provide more
27 pronounced benefits. As a result, travel times for the 2015 Partial Program and
28 2030 Program scenarios are less than those for the 2015 Project and 2030 Project,
29 respectively. In fact, for the 2030 horizon, travel times are reduced by nearly
30 20 percent for the 2030 Program scenario compared to the 2030 Project scenario.

31 **Ballard Bridge to Spokane Street (via Mercer Street and Bored Tunnel)**

32 *Placeholder - waiting for data.*

33 **Northgate to Boeing Access Road (via I-5)**

34 As mentioned in Chapter 5, travel times between Northgate and Boeing Access
35 Road are generally the longest of any route investigated due to the distance
36 covered along the I-5 corridor and the multiple merge/weave sections

1 encountered between these two end points. The modeling results indicate that
2 travel times for the 2015 Partial Program would be nearly identical to those
3 summarized for the 2015 Project scenario. These similar travel times are expected
4 because no major capacity enhancements are incorporated for the SR 99 corridor
5 (outside of the Elliott/Western Connector) that would induce a shift to or away
6 from the I-5 corridor.

7 Mercer Street (I-5 to Elliott Avenue)

8 *Placeholder - waiting for data.*

9 7.1.5 Roadway Connectivity and Access

10 Key Findings

- 11 • The Alaskan Way Viaduct and Seawall Replacement Program would
12 create additional roadway connections and access opportunities that
13 would offer more travel routes in the future.
- 14 • There would be a new roadway connecting Alaskan Way to Elliott and
15 Western Avenues in the area between Pike and Battery Streets.
- 16 • Mercer Street would become two-way from Fifth Avenue to Elliott
17 Avenue W. Roy Street from Aurora Avenue to Queen Anne Avenue
18 would become two-way.

19 Alaskan Way Surface Street Improvements – S. King Street to Pike Street

20 The Alaskan Way surface street would be six lanes wide between S. King and
21 Columbia Streets (not including turn lanes), five lanes between Columbia and
22 Marion Streets (three lanes northbound and two southbound) transitioning to
23 four lanes between Marion and Pike Streets. The new street would include new
24 sidewalks, bicycle lanes, parking and loading zones, and signalized pedestrian
25 crossings at cross streets.

26 Elliott/Western Connector – Pike Street to Battery Street

27 The new roadway connecting Alaskan Way to Elliott and Western Avenues (in
28 the area between Pike and Battery Streets) would be four lanes wide and would
29 provide a grade-separated crossing of the BNSF mainline railroad tracks. The
30 new roadway would include bicycle and pedestrian facilities.

31 The Elliott-Western Connector would provide better connectivity from the
32 waterfront to the Belltown area, which would result in improved access for
33 vehicles and, in particular, freight traffic traveling to and from the
34 Ballard/Interbay/Magnolia areas. This would likely generate higher traffic
35 volumes on Alaskan Way than those experienced today, as access to SR 99 in the
36 Belltown area would be removed by the Bored Tunnel Alternative.

1 Mercer Street West Corridor Improvements – Fifth Avenue to Elliott Avenue
2 Mercer Street would be restriped and resignalized between Fifth Avenue N. and
3 Second Avenue W. to create a two-way street with turn pockets. In addition, Roy
4 Street from Aurora Avenue to Queen Anne Avenue would become two-way.

5 The reconfiguration of the Mercer Street corridor to two-way operations between
6 I-5 and Elliott Avenue W. would provide an improved east-west connection for
7 trips in the north end of the study area. This corridor would also help to reduce
8 circuitous routing for freight vehicles that connect to I-5 at Mercer Street, as well
9 as all westbound vehicles between South Lake Union and Uptown or points west.

10 7.1.6 Transit Services

11 Key Findings

- 12 • Transit ridership for the 2015 Partial Program and 2015 Project would be
13 similar, with a small (about 1 percent) increase under the 2015 Partial
14 Program as compared to the 2015 Project
- 15 • Transit ridership for the 2030 Program and 2030 Project would be similar,
16 with a small (about 1 percent) increase under the 2030 Program as
17 compared to the 2015 Project
- 18 • Along major transit corridors, travel times for the 2015 Program would be
19 comparable to those for the 2015 Project.
- 20 • Along two transit corridors, Ballard/downtown Seattle and Aurora
21 Avenue/downtown Seattle, travel times for the 2030 Program would be
22 comparable to those for the 2030 Project.
- 23 • Since the 2030 Program includes a BAT lane on Aurora Avenue between
24 the Aurora Bridge and Aloha Street, transit travel times along the
25 Aurora/downtown Seattle corridor would likely be less than for general
26 purpose traffic). At 18 mph, travel speeds in the AM peak period are
27 expected to be slow on Aurora Avenue as buses and general traffic
28 approach the segment with the BAT lane.
- 29 • During the AM peak hour, southbound transit travel times from Bridge
30 Way (north end of the Aurora Bridge) to the Harrison Street off-ramp to
31 downtown are projected to be slower in the Program than in the Project
32 due to expected back-ups leading up to the BAT lane, which would slow
33 down transit as well as general purpose traffic.

34 Cumulative effects of the Program would occur under the Partial Program as well
35 as the Full Program. The 2015 Partial Program would include the new Elliott
36 Avenue/Western Avenue Connector and a widened Alaskan Way surface street.

1 Under the 2030 Full Program, northbound and southbound right-side transit
2 lanes on SR 99 are assumed from just south of the Aurora Bridge to north of
3 Aloha Street. Enhanced transit, such as the Delridge RapidRide line, would also
4 be provided along with additional service hours on the West Seattle and Ballard
5 RapidRide lines, peak-hour express routes added to South Lake Union and
6 Uptown, and local bus changes (such as realignments and a few additions) to
7 several West Seattle and northwest Seattle routes. The existing waterfront
8 streetcar line would be replaced by a new streetcar line on First Avenue. In
9 addition, there would be an extension of the South Lake Union Streetcar to
10 connect to the new First Avenue Streetcar.

11 The following sections discuss the estimated effects on transit services of the 2015
12 Partial Program compared to the 2015 Project and the 2030 Full Program
13 compared to the 2030 Project.

14 **Modeled Transit Ridership**

15 Exhibits 7-26 and 7-27 summarize projected daily and AM peak period transit
16 ridership, respectively, at three screenlines: north, central, and south. For the
17 daily and AM peak period, information is presented for the 2015 Project, 2015
18 Partial Program, 2030 Project, and 2030 Program (with BAT lanes).

19 Daily ridership levels for the 2015 Project and 2015 Partial Program would be
20 comparable at each of the screenlines. For the north and south screenlines, there
21 would be slight increase in ridership, and at the Central screenline, there would
22 be a slight decrease in ridership. By 2030, under the Full Program, total daily
23 transit ridership in the study area is forecasted to increase substantially, about
24 45 percent over 2015 levels for the north and central screenlines, and 68 percent
25 for the south screenline. There would be higher ridership levels under the 2030
26 Program as compared to the 2030 Project, but the variation is small, about
27 1 percent. Expanded bus transit services under the King County Metro
28 RapidRide program would affect transit demand at each screenline.

29 For 2015, projected AM peak hour transit demand with the Partial Program
30 would approximate the demand under the Project. There would be higher peak
31 hour ridership levels under the 2030 Program as compared to the 2030 Project, but
32 the variation is small.

1 Exhibit 7-26. Model-Estimated Daily Transit Ridership (person-trips) at Selected
 2 Screenlines – Project and Partial/Full Program

Screenline	2015 Project	2015 Partial Program	2030 Project	2030 Full Program
South (South of S. King Street)	95,800	96,500	163,400	165,300
Central (North of Seneca Street)	124,200	124,800	177,700	180,300
North (North of Thomas Street)	118,600	119,100	170,000	172,600

3 Exhibit 7-27. Model-Estimated AM Peak Transit Ridership (person-trips) at Selected
 4 Screenlines – Project and Partial/Full Program

Screenline	2015 Project	2015 Partial Program	2030 Project	2030 Full Program
South (South of S. King Street)	30,300	30,500	54,500	55,000
Central (North of Seneca Street)	36,100	35,000	53,000	53,700
North (North of Thomas Street)	36,300	36,600	52,700	53,800

5
 6 The transit shares for the Project and Program are identified in Exhibit 7-28.
 7 Under the 2015 scenarios, the transit share of home-based work trips would be
 8 36 percent for the Project and Partial Program. By 2030, this share would increase
 9 to 47 percent under both the Project and the Program. The transit share of non-
 10 work trips in 2015 is estimated to be 9 percent for the Project and Program. By
 11 2030, the transit share for non-work trips would increase to about 11 percent for
 12 the Project and Full Program.

13 Exhibit 7-28. Model-Estimated Daily Transit Mode Shares (person-trips) – To/From
 14 Seattle Center City – 2015 and 2030 Project and Program

	2015 Project	2015 Partial Program	2030 Project	2030 Program
Home-Based Work	36.3	36.3	46.9	47.0
Non-Work	9.4	9.4	11.1	11.2

15 Peak Hour Travel Times – 2015

16 The cumulative effects in 2015 are presented in the following sections for the
 17 major transit corridors that access downtown Seattle. Exhibit 7-29 describes the
 18 2015 travel times for the Project and Partial Program for three major travel
 19 corridors.

1 **Exhibit 7-29. 2015 Travel Times along Major Transit Travel Corridors**

	2015 Project	2015 Partial Program	Change	2015 Project	2015 Partial Program	Change
	AM Peak Hour			PM Peak Hour		
Ballard to Denny Way						
Inbound	9	9	0	8	8	0
Outbound	8	8	0	15	16	+1
Aurora Avenue (Woodland Park to CBD)						
Inbound	18	20	+2	18	18	0
Outbound	12	12	0	17	16	-1
West Seattle to CBD						
Inbound	22	21	-1	17	17	0
Outbound	16	15	+1	25	25	0

2 Peak Hour Travel Times – Ballard/Downtown Seattle

3 Peak hour travel times for the Ballard/downtown Seattle (Denny Way) corridor
 4 would be generally the same for the 2015 Project and 2015 Program. A 1 minute
 5 increase in travel time would occur under the Program in the PM peak hour. For
 6 buses under either scenario, the travel times would likely be less due to the
 7 presence of the bus lane on Elliott Avenue.

8 Peak Hour Travel Times – Aurora Avenue Corridor

9 General traffic conditions on the Aurora Avenue corridor under the 2015 Partial
 10 Program would be comparable to the 2015 Project. Features of the 2015 Partial
 11 Program would not likely affect travel times for both general traffic and transit
 12 along this corridor.

13 Peak Hour Travel Times – West Seattle/Downtown Seattle Corridor

14 The estimated travel times for the Project and Program in 2015 along the West
 15 Seattle/downtown Seattle corridor would be generally similar. With the 2015
 16 Project, access to downtown Seattle via Columbia Street and Seneca Street would
 17 no longer be available. General traffic conditions between West Seattle and
 18 downtown Seattle under the 2015 and 2030 Program would be comparable to the
 19 Project.

20 PM Peak Hour Travel Times – South King County/Downtown Seattle Corridor

21 The travel conditions for the Burien/downtown Seattle travel corridor would be
 22 affected by traffic characteristics in the south end of downtown, particularly the
 23 area between S. Spokane Street and S. King Street. The travel times noted above
 24 for West Seattle/downtown Seattle would apply to the Burien/downtown Seattle
 25 corridor.

1 **Peak Hour Travel Times – 2030**

2 The cumulative effects in 2030 are presented in the following sections for two
 3 major transit travel corridors that provide access to downtown Seattle: Ballard to
 4 Denny Way and Aurora Avenue Exhibit 7-30 describes the 2030 travel times for
 5 the Project and Program (with Aurora BAT lanes) for major transit travel
 6 corridors.

7 **Exhibit 7-30. 2030 Travel Times along Major Transit Travel Corridors**

	2030 Project	2030 Program	Change	2030 Project	2030 Program	Change
	AM Peak Hour			PM Peak Hour		
Ballard to Denny Way						
Inbound	10	9	-1	9	9	0
Outbound	8	8	0	15	19	+4
Aurora Avenue (Aurora Bridge to South Lake Union)						
Inbound		TBD			TBD	
Outbound		TBD			TBD	

8 Peak Hour Travel Times – Ballard/Downtown Seattle

9 Peak hour travel times for the Ballard/downtown Seattle corridor would be
 10 generally the same for the 2030 Project and 2030 Program. A 4-minute increase in
 11 travel time would occur under the Program in the PM peak hour. For buses
 12 under the 2030 Program, the travel times would likely be less under either
 13 scenario due to the presence of the bus lane on Elliott Avenue.

14 Peak Hour Travel Times – Aurora Avenue Corridor

15 With the 2030 Program, a transit lane would be located on Aurora Avenue
 16 between the Aurora Bridge and Aloha Street. With this facility, transit travel
 17 times would likely be less than what is identified for the 2030 Project. Estimated
 18 2030 travel times were reviewed for Aurora Avenue north of the Aurora Bridge.
 19 At 18 mph, travel speeds in the AM peak period are expected to be slow on
 20 Aurora Avenue as buses and general traffic approach the segment with the BAT
 21 lane.

22 **7.1.7 Truck Traffic and Freight**

23 Key Findings

- 24 • The Elliott/Western Connector would greatly improve access for freight
 25 traffic traveling along the central waterfront (Alaskan Way). This
 26 connection would also improve freight travel time by eliminating train
 27 conflicts now experienced at Broad Street and Alaskan Way.

- 1 • Converting Mercer Street to two-way between I-5 and Elliott Avenue W.
2 would provide improved east-west access for freight traffic, particularly
3 streets that serve the Ballard/Interbay/Magnolia areas.
- 4 • Increases in transit services in corridors feeding SR 99 would not directly
5 affect freight operations, although mode shift caused by the transit service
6 expansion would likely reduce vehicle volumes on designated Seattle
7 Center City freight routes.

8 2015 and 2030 Program

9 The combined strategies of the Project (proposed action) and other Program
10 elements should improve freight operations through the study area.

11 In the central waterfront area, the Elliott/Western Connector between Alaskan
12 Way and Elliott and Western Avenues would enhance access for freight traffic
13 from the Magnolia, Interbay, and Ballard areas. This connector would provide
14 two lanes in each direction, beginning at Alaskan Way and Pike Street to Elliott
15 and Western Avenues at about Blanchard Street. A new bridge over the BNSF
16 railroad tracks at Virginia Street would help eliminate conflicts between freight
17 vehicles and train traffic.

18 The Alaskan Way promenade would feature 11-foot travel lanes, with on-street
19 parking, bicycle lanes, and wide sidewalks. Separation of pedestrians and freight
20 vehicles would likely enhance safety in this area.

21 The First Avenue Streetcar project would likely not have a substantial effect on
22 freight operations because most freight traffic would use Alaskan Way and Elliott
23 and Western Avenues along the central waterfront.

24 In the north section of the study area, the enhanced Mercer Street corridor, would
25 improve access for freight traffic; in particular, freight trips from the Magnolia,
26 Interbay, and Ballard areas and I-5. Under the Program definition, Mercer Street
27 extends its two-way operations definition from Fifth Avenue N. on the east all
28 the way to Elliott Avenue W. This may encourage the diversion of some freight
29 traffic from the Nickerson/Westlake Avenue N. freight street.

30 Finally, enhanced transit services in key corridors would not likely affect freight
31 operations. Under the Program scenario, additional service hours would be
32 assigned to the Ballard and West Seattle RapidRide lines. The investments in
33 more transit service beyond currently planned levels would likely increase transit
34 ridership and reduce auto traffic in these corridors. A new RapidRide line, the
35 Delridge line, would be introduced to King County Metro's suite of RapidRide
36 services. This service would help improve transit ridership and reduce auto
37 traffic demand for communities in the Delridge Avenue S.W./White Center
38 corridor.

1 **7.1.8 Parking**

2 Key Findings

- 3 • Several elements of the Program would affect parking along the
4 waterfront, Belltown, and Uptown areas.
- 5 • The Alaskan Way Surface Street Improvements could affect about 580 on-
6 street parking spaces along Alaskan Way and under the viaduct, although
7 some would be replaced.
- 8 • A number of parking mitigation strategies could be implemented to
9 address the cumulative effects of parking disruption, including
10 informational and pricing strategies and an increased supply of short-term
11 visitor and customer parking.

12 This parking section is slightly different from the quantitative approach in Section
13 5.1. This discussion of cumulative effects of the Program is supported by general
14 magnitudes of parking spaces, where data are available. The Program elements
15 that could affect parking are described below. No parking removals are assumed
16 for the First Avenue Streetcar or for transit enhancements.

17 **Alaskan Way Surface Street Improvements**

18 Rebuilding the Alaskan Way surface street between S. King Street and Pike Street
19 would affect parking spaces currently on Alaskan Way and under the viaduct.
20 There are approximately 580 on-street parking spaces on the Alaskan Way surface
21 street and under the viaduct from S. King to Pike Streets. An additional 260 off-
22 street parking spaces nearby could be affected by a street reconfiguration. This
23 totals almost 1,000 parking spaces along the central waterfront that could be
24 affected by the Alaskan Way Surface Street Improvements. A number of these
25 spaces would be replaced, with the number, location, and type of spaces to be
26 determined by the City of Seattle.

27 **Elliott/Western Connector**

28 This project would provide a new roadway connection from Alaskan Way to
29 Elliott and Western Avenues (between Pike and Battery Streets), which would
30 affect the existing parking spaces in this area. This project would affect
31 approximately 280 parking spaces, split equally between on- and off-street
32 parking spaces. Initial estimates indicate that approximately 120 of the 140 on-
33 street parking spaces could be replaced, depending on the final design of the
34 streets.

35 **Mercer Street West Corridor Improvements**

36 Improvements to Mercer Street from Fifth Avenue to Elliott Avenue and
37 improvements to Roy Street from Aurora Avenue to Queen Anne Avenue could

1 affect on-street parking. There are currently about 250 on-street parking spaces
2 on these sections of Mercer and Roy Streets.

3 **Parking Mitigation**

4 Effects on the parking supply would likely be most substantially felt during
5 construction activities along the central waterfront and Pioneer Square. Potential
6 mitigation measures during construction are discussed in Section 7.3.4. Although
7 the mitigation measures would be most needed during construction, many of
8 them could be retained and provide benefits over the longer term. These include:

- 9 • Provide a low rate for the first 4 hours and much higher rates for full-day
10 long-term parking use to encourage short-term visitor/customer parking
11 and discourage long-term employee parking.
- 12 • Encourage privately held parking lots to institute pricing that rewards
13 short-term parking.
- 14 • Build a new parking facility close to the waterfront to provide short-term
15 visitor and customer parking.
- 16 • Coordinate with private and public lots to install real-time automated
17 overhead signs that display where parking is available as drivers enter the
18 central waterfront zone. This is a component of the Center City Parking
19 Program called the Electronic Parking Guidance System.
- 20 • Encourage businesses to use parking vouchers that they could give to
21 customers to park in designated parking lots.

22 **7.1.9 Pedestrians**

23 Key Findings

- 24 • Program elements would improve the pedestrian environment along the
25 waterfront.

26 **2015 and 2030 Program**

27 The Program elements in the central waterfront area would enhance the
28 pedestrian environment with a more pedestrian-focused waterfront that would
29 include a substantial increase in pedestrian space with the proposed promenade
30 along a redesigned Alaskan Way. The new expanded promenade and public
31 space would be provided to the west of the new Alaskan Way surface street
32 between King Street and Pike Street. Between Marion and Pike Streets, this space
33 would be approximately 70 to 80 feet wide.

1 **7.1.10 Bicycles**

2 Key Findings

- 3 • The bicycle environment would be enhanced by the waterfront
4 promenade and the in-street bicycle lanes and sharrows proposed for the
5 new Alaskan Way and Elliott/Western Connector roadways.
- 6 • There would be improved mobility and access in the north project area
7 due to the new street connections over SR 99 and the pedestrian and
8 bicycle paths on the north side of Mercer Street.

9 **2015 and 2030 Program**

10 The Program elements in the waterfront area would enhance the bicycle
11 environment through the reconfiguration of a large portion of the Alaskan Way
12 right-of-way to focus on nonmotorized transportation, with bicyclists able to use
13 the promenade and the in-street bicycle lanes and sharrows proposed for the new
14 Alaskan Way and Elliott/Western Connector roadways.

15 Bicyclists would experience improved access and mobility in the north project
16 area as a result of the new street connections over SR 99 at John, Thomas, and
17 Harrison Streets, as well as the pedestrian and bicycle paths on the north side of
18 Mercer Street. The Mercer Street trail is part of the Potlatch Trail that would
19 connect bicycle facilities in South Lake Union with the Elliott Bay Trail and
20 attractions west of SR 99. Bicycle lanes also would be included on Roy Street.

21 **7.1.11 Ferries**

22 Key Findings

- 23 • Ferries passengers on foot would benefit from the enhanced pedestrian
24 environment along the waterfront.
- 25 • Some of the vehicular traffic to and from the Seattle Ferry Terminal at
26 Colman Dock would have slightly better access due to the new roadway
27 configuration along Alaskan Way and Elliott and Western Avenues.

28 **2015 and 2030 Program**

29 The cumulative effects of the Program on the Washington State Ferries is best
30 described through reference to subgroups of passengers (walk-on passengers and
31 passengers in vehicles).

32 For walk-on passengers who access the terminal on foot, the Program elements
33 along the waterfront would enhance the pedestrian environment through the
34 construction of a more pedestrian-focused waterfront.

1 For ferry passengers in vehicles, the cumulative effect of the Program elements
2 would be limited. The new roadway configuration on Alaskan Way should
3 slightly improve access to the terminal but the overall surface street network in
4 downtown Seattle would remain substantially the same.

5 7.1.12 Safety

6 Key Findings

- 7 • The safety benefits of the Program would be similar to those of the project.

8 2015 and 2030 Program

9 For the 2015 and 2030 Program, the safety benefits would be similar to those of
10 the project. However, several elements of the Program could lead to an increased
11 potential for conflicts between vehicles and pedestrians or bicycles. The
12 Elliott/Western Connector would result in increased traffic along Elliott Avenue,
13 Western Avenue, and Alaskan Way, and the potential for conflicts between
14 vehicles and pedestrians/bicycles could increase on those roadways. The Mercer
15 Street west corridor improvements would convert Mercer and Roy Streets to two-
16 way. Generally, two-way streets are safer for pedestrians as the traffic moves at a
17 slower rate of speed. However, if intersections are unsignalized, crossing two-
18 way streets can be more complicated for pedestrians, because pedestrians have to
19 look for traffic from two directions instead of only one.

20 7.1.13 Event Traffic

21 Key Findings

- 22 • No substantial changes in the south portal area are expected beyond those
23 attributed to the project.
- 24 • The two-way Mercer configuration would allow more direct access to the
25 Seattle Center parking garages north of Mercer Street from the east.
26 However, in terms of egress capacity after events at the Seattle Center, the
27 two-way system may result in slightly longer travel times and greater
28 delays.
- 29 • The connections between the central waterfront (Alaskan Way) and
30 Elliott/Western would greatly improve access for events and would likely
31 shift some event traffic away from the bored tunnel to surface streets.

32 South Portal Area

33 Under the 2030 Program scenario, no substantial changes in the south end beyond
34 those identified for the 2030 Project would occur in terms of roadway network
35 components and connections to/from regional facilities. Therefore, no major

1 differences for event traffic in terms of detour routing, congestion levels, and/or
2 requirements for traffic management would result.

3 **North Portal Area**

4 No substantial roadway changes in the north end are expected between the 2030
5 Project and 2030 Program, with the exception of two elements: (1) conversion of
6 Mercer Street (and Mercer Place) to two-way operations west of Fifth Avenue N.
7 to Elliott Avenue and (2) new connections from Alaskan Way to/from Elliott/
8 Western Avenues. The Mercer Street reconfiguration would complete the two-
9 way conversion initiated by the Mercer Corridor Project and the Alaskan Way
10 Viaduct Replacement Project phases.

11 With regard to event traffic, the two-way Mercer configuration would allow more
12 direct access to the Seattle Center parking garages north of Mercer Street from the
13 east (e.g., I-5) by eliminating the need to use the one-way couplet system of Roy
14 and Mercer Streets. However, in terms of egress capacity after events at the
15 Seattle Center, the two-way system may result in slightly longer travel times and
16 greater delays compared to a traditional one-way system due to the need to serve
17 a larger number of movements at nearby intersections/signals between Queen
18 Anne Avenue and Fifth Avenue N.

19 The connections between the central waterfront (Alaskan Way) and Elliott/
20 Western would greatly improve access for events and would likely shift some
21 event traffic way from the bored tunnel to surface streets. Diversion to local
22 streets may increase congestion levels slightly on Broad Street and cross streets
23 such as First Avenue N. compared to Project conditions.

24 **7.2 Comprehensive Cumulative Effects**

25 The focus of the comprehensive cumulative effects analysis is on the combined
26 effect of the project (proposed action), other Program elements, and other projects
27 that are anticipated to add to transportation effects in the study area. This entire
28 section is approached qualitatively. The following projects are included for
29 consideration of comprehensive cumulative effects:

30 **A. Roadway Elements**

- 31 • Alaskan Way Surface Street Improvements – S. King Street to Pike Street
- 32 • Elliott/Western Connector – Pike Street to Battery Street
- 33 • Mercer Street Improvements – (conversion of Mercer Street from Fifth
34 Avenue to Elliott Avenue to two-way and conversion of Roy Street from
35 Aurora Avenue to Queen Anne Avenue to two-way)
- 36 • Battery Street Tunnel maintenance and repairs

1 **B. Non-Roadway Elements**

- 2 • Seawall Replacement
- 3 • Alaskan Way Promenade
- 4 • Transit Enhancements – (1) Delridge RapidRide and (2) additional service
- 5 hours on West Seattle and Ballard RapidRide
- 6 • First Avenue Streetcar

7 **C. Projects under Construction**

- 8 • Transportation Improvements to Minimize Traffic Effects during
- 9 Construction

10 **D. Completed Projects**

- 11 • Column Safety Repairs
- 12 • Electrical Line Relocation along the Viaduct’s South End

13 **E. Seattle Planned Urban Development**

- 14 • Gull Industries on First Avenue S.
- 15 • North Parking Lot Development at Qwest Field
- 16 • Seattle Center Master Plan (EIS) (Century 21 Master Plan)
- 17 • Bill and Melinda Gates Foundation Campus Master Plan
- 18 • South Lake Union Redevelopment
- 19 • U.S. Coast Guard Integrated Support Command
- 20 • Seattle Aquarium and Waterfront Park
- 21 • Seattle Combined Sewer System Upgrades

22 **F. Local Roadway Improvements**

- 23 • Bridging the Gap Projects
- 24 • S. Spokane Street Widening
- 25 • SR 99/East Marginal Way Grade Separation
- 26 • Mercer Corridor Improvements from Dexter Avenue to I-5
- 27 • SR 519 Intermodal Access Project, Phase 2

28 **G. Regional Roadway Improvements**

- 29 • I-5 Reconstruction
- 30 • SR 520 Bridge Replacement and HOV Program

- 1 • I-405 Corridor Program
- 2 • I-90 Two-Way Transit and HOV Operations, Stages 1 and 2

3 **H. Transit Improvements**

- 4 • First Hill Streetcar
- 5 • University Link Light Rail Project
- 6 • RapidRide
- 7 • Sound Transit North Link
- 8 • Sound Transit East Link

9 **I. Transportation Network Assumptions**

- 10 • Change in HOV definition to 3+ for the Puget Sound region
- 11 • Sound Transit
- 12 • Other transit improvements

13 **J. Completed, but Relevant Projects**

- 14 • Central Link Light Rail (including the Sea-Tac Airport extension)
- 15 • South Lake Union Streetcar

16 Several projects, such as the S. Holgate Street to S. King Street Viaduct
17 Replacement, Fourth Avenue S. Loop Ramp, and S. Spokane Street Widening, are
18 included in the Baseline conditions, so they are not considered in this section for
19 comprehensive cumulative effects.

20 Key Findings

- 21 • Comprehensive cumulative effects are generally similar to the effects of
22 the Program.
- 23 • Overall, increased transit service, whether it is provided by bus, light rail,
24 or commuter rail, would help in reducing SOV demand to the Center City
25 and reduce the growth rate of demand on SR 99, I-5, and local arterials for
26 years to come.
- 27 • As other major regional transportation improvements are completed,
28 traffic operations on SR 99 are expected to improve.
- 29 • Intersection congestion levels under the comprehensive 2030 Program,
30 with the combined effects of regional projects, would likely be similar to
31 or lower than those for the 2030 Program scenario in terms of average
32 vehicle delays and LOS.

1 7.2.1 Regional Context and Travel Patterns

2 Most of the projects considered for comprehensive cumulative effects would not
3 have a substantial effect on the larger region or regional travel patterns.
4 However, the transit improvements are worth noting. A longer Link light rail
5 system connecting the Eastside and extending at least to Lynnwood in the north
6 and a more complete King County Metro RapidRide system, coupled with
7 additional transit service hours, would increase the person-carrying capacity of
8 the Center City screenlines. Overall, increased transit service, whether provided
9 by bus, light rail, or commuter rail, would help in reducing SOV demand to the
10 Center City and reduce the growth rate of demand on SR 99, I-5, and local
11 arterials for years to come.

12 7.2.2 Traffic Operations on SR 99

13 The improvements related to the Project, Program, and other area projects would
14 have a substantial effect on traffic operations on SR 99. As discussed previously,
15 the Bored Tunnel Alternative is expected to result in operations that are similar to
16 or better than Baseline conditions between South Lake Union and the stadium
17 area. On Aurora Avenue, the reduced roadway capacity with the addition of the
18 BAT lanes is expected to result in degraded traffic operations, both for general
19 purpose traffic and transit vehicles.

20 As other major regional transportation improvements are completed, traffic
21 operations on SR 99 are expected to improve. For example, reconstruction of I-5
22 is expected to include restriping which would provide higher capacity through
23 downtown Seattle. In addition, the extension of Link light rail north to
24 Lynnwood and south to Federal Way would provide additional person-carrying
25 capacity. The additional capacity on these other facilities would help relieve
26 demand on SR 99.

27 7.2.3 Traffic Operations at Key Arterial Intersections

28 Intersection congestion levels under the comprehensive 2030 Program, with the
29 combined effects of regional projects, would likely be similar to or lower than the
30 2030 Program scenario (described previously in Section 7.1) in terms of average
31 vehicle delays and LOS. Traffic demand and peak hour volumes along the SR 99
32 corridor and at intersections within the three sub-areas investigated under the
33 Program would either remain consistent with 2030 Program levels or decrease
34 slightly once the regional projects completed. As discussed in Section 7.1, the
35 transit enhancements proposed for the 2030 Program may induce only minor
36 shifts to non-automobile-based modes such as light rail or bus and, therefore,
37 modestly affect general purpose traffic levels and congestion on arterials and
38 highway facilities.

1 However, with additional transit resources and services included as part of the
2 comprehensive regional transportation system, such as completion of the Sound
3 Transit streetcar program in the downtown area, Link light rail extensions to the
4 north and east, implementation of Metro’s Paid Ride system, and completion of
5 the HOV system, the mode shift to transit services would be substantially more
6 pronounced than under the 2030 Program scenario. In principle, the ubiquity of
7 transit services may increase overall ridership and potentially encourage a sizable
8 portion of regional trips to shift away from conventional automobile-based
9 alternatives (SOV, HOV, etc). In the event that major transit patronage is realized
10 with the long-range systems in place for the comprehensive program, traffic
11 volumes in the downtown core and on regional facilities such as SR 99 could
12 conceivably decrease from 2030 Program levels. Consequently, intersection
13 delays and sub-area congestion could be reduced due to lower peak hour
14 demands on local streets and arterials.

15 Benefits due to improvements to regional highway corridors such as I-405,
16 SR 520, and I-90 may also serve as a means for reducing traffic volumes along I-5
17 and possibly SR 99. With greater options for regional travel in terms of high-
18 capacity corridors and alternative modes, the probability of reduced demand on
19 the SR 99 corridor would likely increase. Again, such decreases in traffic volume
20 for affected intersections within the sub-areas evaluated would translate to
21 reduced levels of delay, decreased congestion, and improvements in point-to-
22 point travel times.

23 7.2.4 Roadway Connectivity and Access

24 The combined effects of the Alaskan Way Viaduct Replacement Project and other
25 roadway, transit, and non-roadway improvements would result in improved
26 accessibility and connectivity. In addition to the Program elements, several
27 projects would improve connectivity and access. The most benefits in terms of
28 connectivity would be provided by the local roadway improvements, including
29 the Bridging the Gap Projects, the S. Spokane Street Widening, the SR 99/East
30 Marginal Way Grade Separation, the Mercer Street Improvements, and the SR 519
31 Intermodal Access Project – Phase 2.

32 7.2.5 Transit Services

33 Indirect and cumulative effects involving transit include future development of
34 regional HCT facilities and service. With voter approval of the ST2 Plan in
35 November 2008, Link light rail serving downtown Seattle will be extended to
36 serve Lynnwood in the north, Redmond (Overlake) in the east, and Federal Way
37 in the south. Also, additional trips and system capacity will be provided on

1 Sounder commuter rail service operating between Lakewood and downtown
2 Seattle.

3 Potential new passenger-only ferry connections to downtown Seattle may be
4 provided by the King County Ferry District. These connections would be based
5 on the results of a feasibility study of potential expanded passenger-only ferry
6 service within King County. Potential new routes include Ballard (Shilshole) to
7 downtown Seattle (Pier 50) and Des Moines to downtown Seattle.

8 7.2.6 Truck Traffic and Freight

9 The combined strategies of the Project (proposed action) and other Program
10 elements should improve freight operations through the study area, as described
11 previously. Other projects in the vicinity would further improve conditions.

12 Although the SR 99/East Marginal Way Grade Separation project is included in
13 the Baseline conditions, it is worth noting. This project, which is located on
14 Duwamish Avenue between S. Spokane Street and E. Marginal Way, would
15 improve freight access among the Port of Seattle terminals, UPRR and BNSF rail
16 yards, and local manufacturers' and distribution warehouses. The lead track will
17 be grade-separated and connect on-dock rail at the Port of Seattle's Terminal 5
18 (where containers are loaded directly onto trains instead of shuttled to a railyard
19 by truck) to the mainline. It will also support industrial users in West Seattle and
20 on Harbor Island. The project would improve safety by eliminating rail/highway
21 conflicts at the existing at-grade crossing, reduce vehicle delay at railroad tracks
22 by grade separation, and facilitate greater efficiencies in an area of substantial
23 intermodal and multimodal activity.

24 7.2.7 Parking

25 Cumulative effects relating to parking would largely be experienced during
26 construction if parking is disrupted. Effects on parking during construction are
27 discussed in Section 7.3.4. Beyond the effects on parking related to the Program
28 elements, none of the projects considered for comprehensive cumulative effects is
29 anticipated to have a substantial effect on parking.

30 7.2.8 Pedestrians

31 The addition of the new roadway connections across existing pedestrian barriers
32 such as SR 99 in the northern portion of the study area, improvements to
33 pedestrian facilities and amenities, and greater consideration of the pedestrian
34 experience in the project area may enhance overall nonmotorized and transit
35 travel within and to the downtown Seattle area, contributing to the achievement

1 of the region's goal of reduced automobile travel, decreased traffic congestion,
2 and improvements in other overall quality of life measures, such as air quality.

3 7.2.9 Bicycles

4 The addition of new bicycle facilities in the southern portion of the study area and
5 a substantial increase in bicycle connections across SR 99 to other major bicycle
6 facilities may increase nonmotorized travel and transit travel in the Greater
7 Seattle area, contributing to an overall decrease in dependence on automobiles
8 and improvements in congestion, air quality, and other quality of life measures.

9 7.2.10 Ferries

10 For walk-on ferry passengers who access the terminal on foot, the elimination of
11 the Alaskan Way Viaduct, enhancements to the pedestrian environment adjacent
12 to and through the Alaskan Way surface street, along with the other transit
13 enhancements in the city such as the Link light rail system and the Third Avenue
14 transit corridor should improve daily conditions and encourage continued
15 increases in nonmotorized travel.

16 For ferry passengers in vehicles, the cumulative effect of all the projects expected
17 to be in place when the bored tunnel is completed would be limited.

18 7.2.11 Safety

19 The overall cumulative effects related to safety would be similar to those for the
20 Program. Several of the projects considered for cumulative effects could improve
21 safety. For example, the SR 99/East Marginal Way Grade Separation project
22 would eliminate rail/highway conflicts at the existing at-grade crossing. The
23 SR 519 Intermodal Access Project – Phase 2, improvements would separate
24 automobile, freight, pedestrian, and rail traffic to help improve mobility,
25 pedestrian safety, and reduce the risk of collisions.

26 7.2.12 Event Traffic

27 South Portal Area

28 Cumulative effects on event traffic in the stadium area would be mainly driven by
29 changes in land use and transit modes. With the initiation of Link light rail
30 service in mid-2009, the continuing improvements to Sounder commuter rail
31 trains on weekends, and potential future bus service enhancements, it is
32 anticipated that more event-goers would begin to gravitate toward non-
33 automobile transportation options as their preferred alternative for going to and
34 from the stadiums. This transition would not be immediate; it would occur over
35 several years.

1 Land use changes such as the potential development of the Qwest Field north lot
2 could also influence traffic demands by reducing the parking supply and thereby
3 encouraging alternative modes, such as transit and walking.

4 North Portal Area

5 Similar to the south end, event traffic impacts due to cumulative effects in the
6 north end would be influenced primarily by changes in land use and transit
7 modes. Future streetcar service between downtown and the Seattle Center as
8 well as expanded RapidRide BRT service may be provided by the time the
9 Alaskan Way Viaduct and Seawall Replacement Program is completed. Such
10 changes in the transportation system accompanied by increased densification of
11 land uses near the Seattle Center may influence a shift to non-automobile travel
12 modes and help to offset future (and inevitable) increases in background traffic
13 demands during major events.

14 7.3 Cumulative Effects During Construction

15 Key Findings

- 16 • One of the benefits of the Project is that it minimizes construction effects
17 (both Project-specific and cumulative) by allowing the existing Alaskan
18 Way Viaduct to stay in operation until the bored tunnel is completed.
- 19 • There are a number of other major transportation projects in the vicinity of
20 the bored tunnel that would occur during the Project's construction
21 period.
- 22 • Disruptions due to the Project would primarily occur at or near the tunnel
23 portals.
- 24 • Traffic patterns in the project area are complex and schedule adjustments
25 made during the construction of any of the overlapping projects have the
26 potential to affect other projects and traffic patterns.

27 This section describes qualitatively any notable cumulative effects that could
28 occur during construction, considering the entire Alaskan Way Viaduct and
29 Seawall Replacement Program and other projects in the general vicinity. There
30 are numerous projects underway in the Puget Sound region that have the
31 potential to affect a small portion of trips on the Alaskan Way Viaduct (e.g., the
32 SR 520 bridge replacement project or the completion of the Central Link portion
33 of the Sound Transit light rail line). This section discusses only projects that are
34 relatively close to the bored tunnel and also occurring during the construction
35 period of the Bored Tunnel Alternative.

1 For the purposes of this section of the Transportation Discipline Report, the
2 following projects are discussed for their potential to affect the Bored Tunnel
3 Alternative:

- 4 • Major components of the Program that are not included in the Bored
5 Tunnel Alternative and would overlap with respect to construction timing
6 and proximity include:
 - 7 ○ Alaskan Way Surface Street Improvements – S. King Street to Pike
8 Street
 - 9 ○ Elliott/Western Connector – Pike Street to Battery Street
 - 10 ○ Mercer Street Improvements
 - 11 ○ Seawall Replacement
 - 12 ○ Alaskan Way Promenade
 - 13 ○ S. Holgate Street to S. King Street Viaduct Replacement
- 14 • City of Seattle projects
 - 15 ○ Bridging the Gap Projects
 - 16 ○ S. Spokane Street Widening
 - 17 ○ Mercer Street Corridor Program

18 The use of tunnel boring technology instead of a cut-and-cover method eliminates
19 many of the construction effects in the center of the project area. Therefore, the
20 cumulative effects due to construction of the bored tunnel and other nearby
21 concurrent projects are best described at each end of the project area where
22 connections need to be made to the tunnel and the tunnel boring machine enters
23 and exits the ground, at the Elliott/Western Connector, in the area of the seawall
24 replacement, and for the viaduct demolition activities.

25 7.3.1 South Portal Area

26 Three projects have the potential to generate construction-related effects on the
27 Project in the vicinity of the south portal of the tunnel: S. Spokane Street
28 Widening project, S. Holgate Street to S. King Street Viaduct Replacement Project,
29 and the SR 519 Intermodal Access Project – Phase 2.

30 Although the Spokane Street Widening project is not adjacent to the south portal
31 of the bored tunnel and it is farther away than the other two projects (about 1 mile
32 south), it does have the potential to affect users of the SR 99 corridor and
33 indirectly the bored tunnel. In particular, the closure of the southbound to
34 westbound ramp from Fourth Avenue S. has the potential to divert some traffic
35 that is current using Fourth Avenue for access to West Seattle to drive through
36 the construction area on First Avenue. The completion of a ramp from the
37 eastbound lanes of the Spokane Street Viaduct to Fourth Avenue S. (in particular
38 the northbound movement) could benefit the Bored Tunnel Alternative by

1 providing a more efficient connection to Fourth Avenue and additional incentive
2 for drivers to avoid the construction zone on First Avenue.

3 Construction activities on the S. Holgate Street to S. King Street Viaduct
4 Replacement project would overlap with the construction of the Bored Tunnel
5 Alternative from about 2011 through 2014. In particular, the current schedules
6 require lane closures on First Avenue between Railroad Way S. and S. King Street
7 near the time that the S. Holgate Street to S. King Street Viaduct Replacement
8 Project would be closing Alaskan Way from Railroad Way S. to S. Atlantic Street.
9 If schedule adjustments during construction force the closure of Alaskan Way to
10 occur when First Avenue S. is reduced to one lane, there would be a substantial
11 effect on north-south traffic in the south portal area.

12 As part of the S. Holgate Street to S. King Street Viaduct Replacement Project,
13 S. Royal Brougham Way would be closed east of Alaskan Way S. throughout the
14 construction period, and it would remain closed thereafter. A portion of the
15 roadway west of First Avenue S. would remain open to provide access to adjacent
16 businesses and the temporary on-ramp to northbound SR 99. In this way,
17 business access would not be directly affected. Users who normally use S. Royal
18 Brougham Way to travel east-west between Alaskan Way S. and the stadium area,
19 SR 519, or First Avenue S. would instead use S. King Street to the north or
20 S. Atlantic Street one block to the south.

21 The SR 519 project would be substantially complete before construction related to
22 the Bored Tunnel Alternative begins. However, there is the potential for several
23 months of overlap between the two projects in the vicinity of S. Royal Brougham
24 Way and First Avenue S. Although the projects are not adjacent to each other,
25 there is the potential for additional effects on traffic due to construction vehicles
26 and potential lane closures on S. Royal Brougham Way.

27 7.3.2 Central Area

28 In the central waterfront area between S. Washington Street and Pike Street the
29 Alaskan Way Seawall Replacement Project would close sections of Alaskan Way
30 over a 3-year period between 2012 and 2015. Construction of the seawall and the
31 associated effects on Alaskan Way are planned to be complete prior to the
32 demolition of the Alaskan Way Viaduct. However, construction of the seawall
33 would run concurrently with the Bored Tunnel Alternative, and there would
34 likely be both lane closures and detours or realignments of Alaskan Way between
35 S. Washington Street and Pike Street that occur during construction of the Bored
36 Tunnel Alternative.

37 Along with affecting general purpose traffic, there are anticipated to be effects on
38 freight operations along Alaskan Way during project construction. WSDOT, City,

1 and Port of Seattle will be working collectively to develop construction staging
2 plans for the Seawall Replacement Project.

3 7.3.3 North Portal Area

4 The primary project that requires discussion in the north portal area is the Mercer
5 Street Corridor Improvements program. In this project, the City of Seattle would
6 be widening and modifying Mercer Street from its current one-way configuration
7 to a two-way operation.

8 The Two-Way Mercer Corridor project consists of several major components. The
9 section from Dexter Avenue to I-5 is part of the baseline conditions and is
10 scheduled to be completed before the construction for the Bored Tunnel
11 Alternative begins. As part of the Dexter Avenue to I-5 improvements, Broad
12 Street would be closed between Taylor Avenue N. and Ninth Avenue N., and
13 Mercer Street would be converted to two-way traffic between I-5/Fairview
14 Avenue N. and Fifth Avenue N. If any delays occur, construction activities
15 would need to be coordinated with the portions of the Bored Tunnel Alternative
16 that affect Mercer Street.

17 At a later date, Mercer Street would be converted to two-way traffic operations
18 between Elliott Avenue W. and Fifth Avenue N. The timing of this portion of the
19 program has not yet been determined and it is unclear whether any of the
20 construction would overlap with the Bored Tunnel Alternative.

21 7.3.4 Parking

22 The Program is expected to have a more substantial effect on parking than the
23 Project alone, with the cumulative effects from all of the Program elements
24 supporting consideration for parking mitigation. A number of parking mitigation
25 strategies could be implemented to address parking disruption due to
26 construction activities. Cumulative effects and potential mitigation strategies are
27 discussed below.

28 Cumulative Effects on Parking During Construction

29 Seawall Replacement

30 The Seawall Replacement project is not anticipated to permanently affect parking.
31 However, there may be substantial effects on parking during construction,
32 depending on whether parking on the Alaskan Way surface street would be
33 removed and whether parking under the viaduct would need to be removed to
34 accommodate additional travel lanes under the viaduct. There are approximately
35 580 on-street parking spaces on the Alaskan Way surface street and under the
36 viaduct from S. King Street to Pike Street.

1 In addition to the parking on Alaskan Way and under the viaduct, parking on the
2 piers also could be affected during seawall construction activities. There are
3 about 80 parking spaces on Piers 53, 54, 56, and 57, in addition to loading zones
4 on many of the piers. Most of these parking spaces are employee and visitor
5 spaces for businesses on the piers.

6 Alaskan Way Surface Street Improvements

7 Rebuilding the Alaskan Way surface street between S. King Street and Pike Street
8 would affect parking spaces currently on Alaskan Way and under the viaduct. It
9 is likely that this project would begin work immediately after the viaduct
10 demolition. Therefore, it is possible that the parking under the viaduct and along
11 Alaskan Way may not return to use immediately after viaduct demolition. There
12 are approximately 580 on-street parking spaces on the Alaskan Way surface street
13 and under the viaduct from S. King Street to Pike Street. There are an additional
14 260 off-street parking spaces nearby that could be affected by a street
15 reconfiguration. This totals almost 1,000 parking spaces along the central
16 waterfront that could be affected by the Alaskan Way surface street
17 improvements. A number of these spaces would be replaced, with the number,
18 location, and type of spaces to be determined by the City of Seattle.

19 Other Projects

20 Construction activity related to private development may occur concurrently with
21 Project or Program construction and could affect the supply of parking,
22 particularly in off-street (pay) parking lots. In particular, there are several
23 developments in the stadium area that could affect parking within the timeframe
24 of the Program.

25 The Qwest Field north lot redevelopment could affect 1,100 spaces during
26 construction, but preliminary information on the redevelopment indicates that
27 about 950 spaces would be included in the new development. If the north lot
28 redevelopment removes parking spaces at the same time that the Program affects
29 parking spaces along the waterfront and in Pioneer Square, there could be a
30 noticeable shortage of parking in Pioneer Square.

31 The redevelopment of Home Plate Parking at S. Atlantic Street and First Avenue
32 S. could affect 300 off-street parking spaces during construction. About 610
33 spaces are proposed for the new development, although not all of these would be
34 available to the public. The main effect of this redevelopment on parking would
35 be felt during construction, when 300 spaces are removed.

1 **Parking Mitigation During Construction**

2 Potential Mitigation Strategies for the Central Waterfront/Pioneer Square Areas

3 A number of parking mitigation strategies could be implemented to address the
4 cumulative effects of parking disruption due to construction activities along the
5 central waterfront and in Pioneer Square. Strategies such as the following would
6 need to be coordinated between WSDOT and the City of Seattle, with input from
7 surrounding businesses:

- 8 • Provide pedestrian and parking maps in advance of and during
9 construction for businesses (at no cost to the businesses) to mail to clients
10 and vendors.
- 11 • Increase the short-term maximum meter time from 2 hours to at least
12 3 and possibly 4 hours since the average trip to the waterfront is estimated
13 at 3 to 4 hours.
- 14 • Provide a low rate for the first 4 hours and much higher rates for full-day
15 long-term parking use to encourage short-term visitor/customer parking
16 and discourage long-term employee parking.
- 17 • Encourage privately held parking lots to institute pricing that rewards
18 short-term parking.
- 19 • Build a new parking facility close to the waterfront to provide short-term
20 visitor and customer parking.
- 21 • Coordinate with private and public lots to install real-time automated
22 overhead signs that display where parking is available as drivers enter the
23 central waterfront zone.
- 24 • Encourage businesses to use parking vouchers that they can give to
25 customers for parking in designated parking lots.

26 Center City Parking Program

27 The Center City Parking Program is SDOT's approach for addressing changes
28 and growing demand for short-term parking in the Seattle Center City area over
29 the next several years. Marketing, way-finding, and technology measures aim to
30 improve access to off-street short-term parking beginning in 2012. The approach
31 is designed to keep the Center City area moving as more jobs and people come to
32 Seattle, and throughout the construction of the Alaskan Way Viaduct
33 Replacement Project.

34 One innovative component of the Center City Parking Program is the Electronic
35 Parking Guidance System, which uses signs to provide motorists with
36 information about real-time parking space availability and directs them from
37 primary downtown access points to parking garages. This new technology

1 would make it easy for shoppers and visitors to find parking and reduce traffic
2 congestion and pollution by reducing the time spent circling for vacant on-street
3 parking. The Electronic Parking Guidance System project will begin as a pilot
4 project focused on the retail and Pike Place Market areas to test the technology
5 and concept beginning in the spring of 2010.

6 To support the launch of the Electronic Parking Guidance System in spring 2010,
7 SDOT is developing a marketing strategy and program name and branding to be
8 used on message signs, a parking locator website, printed maps, and marketing
9 programs for participating garages, properties, and other organizations in the
10 Seattle Center City area.

11 Potential Mitigation Strategies for Construction Worker Parking

12 As described previously for construction worker parking for the project, the same
13 strategies could help minimize the use of visitor/customer parking by
14 construction workers for the overall Program:

- 15 • Develop a plan for construction worker parking to identify appropriate
16 parking options for construction workers and discourage use of short-
17 term visitor/customer parking in the project vicinity.
- 18 • Provide strong enforcement of the short-term parking regulations in the
19 immediate project area (within a two- to three-block radius). The goal is
20 to ensure a constant supply of short-term parking for customers of central
21 waterfront businesses and to prevent use of these spaces by construction
22 workers.
